## Type Package

Title Nonparametric Varying Coefficient Spike-and-Slab Lasso
Version 2.0
Date 2023-09-17
Author Ray Bai
Maintainer Ray Bai [raybaistat@gmail.com](mailto:raybaistat@gmail.com)
Description Fits Bayesian regularized varying coefficient models with the Nonparametric Varying Coefficient Spike-and-Slab Lasso (NVC-SSL) introduced by Bai et al. (2023) [arXiv:1907.06477](arXiv:1907.06477). Functions to fit frequentist penalized varying coefficients are also provided, with the option of employing the group lasso penalty of Yuan and Lin (2006) [doi:10.1111/j.14679868.2005.00532.x](doi:10.1111/j.14679868.2005.00532.x), the group minimax concave penalty (MCP) of Breheny and Huang [doi:10.1007/s11222-013-9424-2](doi:10.1007/s11222-013-9424-2), or the group smoothly clipped absolute deviation (SCAD) penalty of Breheny and Huang (2015) [doi:10.1007/s11222-013-9424-2](doi:10.1007/s11222-013-9424-2).License GPL-3LazyData trueDepends R (>= 3.6.0)Imports stats, splines, dae, plyr, Matrix, GIGrvg, MASS, MCMCpack,grpreg, mvtnorm

NVC_frequentist Fits frequentist penalized nonparametric varying coefficient (NVC) models

## Description

This function implements frequentist penalized nonparametric varying coefficient (NVC) models. It supports the following penalty functions: the group lasso penalty of Yuan and Lin (2006), the group minimax concave penalty (MCP) of Breheny and Huang (2015), and the group smoothly clipped absolute deviation (SCAD) penalty of Breheny and Huang (2015). This function solves a penalized regression problem of the form,

$$
\operatorname{argmax}_{\gamma} \frac{1}{N} \ell(\gamma)+\operatorname{pen}_{\lambda}(\gamma)
$$

where $N$ is the total number of observations, $\ell(\gamma)$ is the loss function, and $p e n_{\lambda}(\cdot)$ is a penalty function with regularization parameter $\lambda>0$. Since the objective function is rescaled by $1 / N$, the penalty $\lambda$ is typically smaller than the spike hyperparameter $\lambda_{0}$ used by the NVC_SSL function. The BIC criterion is used to select the optimal tuning parameter $\lambda$.

## Usage

NVC_frequentist(y, t, X, n_basis=8, penalty=c("gLASSO", "gSCAD", "gMCP"),
lambda=NULL, include_intercept=TRUE)

## Arguments

y $\quad N \times 1$ vector of response observations $y_{11}, \ldots, y_{1 m_{1}}, \ldots, y_{n 1}, \ldots, y_{n m_{n}}$
$\mathrm{t} \quad N \times 1$ vector of observation times $t_{11}, \ldots, t_{1 m_{1}}, \ldots, t_{n 1}, \ldots, t_{n m_{n}}$
X $\quad N \times p$ design matrix with columns $\left[X_{1}, \ldots, X_{p}\right]$, where the $k$ th column contains the entries $x_{i k}\left(t_{i j}\right)$ 's
n _basis number of basis functions to use. Default is $\mathrm{n} \_$basis=8.
penalty string specifying which penalty function to use. Specify "gLASSO" for group lasso, "gSCAD" for group SCAD, or "gMCP" for group MCP.
lambda grid of tuning parameters. If lambda is not specified (i.e. lambda=NULL), then the program automatically chooses a grid for lambda. Note that since the objective function is scaled by $1 / N$, the automatically chosen grid for lambda typically consists of smaller values than the default grid for lambda0 used by the function NVC_SSL.
include_intercept
Boolean variable for whether or not to include an intercept function $\beta_{0}(t)$ in the estimation. Default is include_intercept=TRUE.

## Value

The function returns a list containing the following components:
t_ordered all $N$ time points ordered from smallest to largest. Needed for plotting.
classifications
$p \times 1$ vector of indicator variables, where " 1 " indicates that the covariate is selected and " 0 " indicates that it is not selected. These classifications are determined by the optimal lambda chosen from BIC. Note that this vector does not include an intercept function.
beta_hat $\quad N \times p$ matrix of the estimates for varying coefficient functions $\beta_{k}(t), k=$ $1, \ldots, p$, using the optimal lambda chosen from BIC. The $k$ th column in the matrix is the $k$ th estimated function at the observation times in $t$ _ordered.
beta0_hat estmate of the intercept function $\beta_{0}(t)$ at the observation times in $t_{\text {_order }}$ for the optimal lambda chosen from BIC. This is not returned if include_intercept = FALSE.
gamma_hat estimated basis coefficients (needed for prediction) for the optimal lambda.
lambda_min the individual lambda which minimizes the BIC. If only one value was originally passed for lambda, then this just returns that lambda.
lambda0_all grid of all $L$ regularization parameters in lambda. Note that since the objective function is scaled by $1 / N$ for the penalized frequentist methods in the NVC_frequentist function, the lambda_all grid that is chosen automatically by NVC_frequentist typically consists of smaller values than the default values in the lambda0_all grid for NVC_SSL.

BIC_all $L \times 1$ vector of BIC values corresponding to all $L$ entries in lambda_all. The $l$ th entry corresponds to the $l$ th entry in lambda_all.
beta_est_all_lambda
list of length $L$ of the estimated varying coefficients $\beta_{k}(t), k=1, \ldots, p$, corresponding to all $L$ lambdas in lambda_all. The $l$ th entry corresponds to the $l$ th entry in lambda_all.
beta0_est_all_lambda
$N \times L$ matrix of estimated intercept function $\beta_{0}(t)$ corresponding to all $L$ entries in lambda_all. The $l$ th column corresponds to the $l$ th entry in lambda_all. This is not returned if include_intercept=FALSE.
gamma_est_all_lambda
$d p \times L$ matrix of estimated basis coefficients corresponding to all entries in lambda_all. The $l$ th column corresponds to the $l$ th entry in lambda_all.
classifications_all_lambda
$p \times L$ matrix of classifications corresponding to all the entries in lambda_all. The $l$ th column corresponds to the $l$ th entry in lambda_all.
iters_to_converge
number of iterations it took for the group ascent algorithm to converge for each entry in lambda_all. The $l$ th entry corresponds to the $l$ th entry in lambda_all.

    xlab="Time", ylim = c(0,15), ylab=expression(beta[5]))
```

## Description

This is a function to predict the responses $y\left(t_{\text {new }}\right)$ for new subjects at new time points $t_{\text {new }}$ with new covariates $X_{\text {new }}$. The function accepts an estimated NVC model that was fit using either the NVC_SSL or NVC_frequentist functions and returns the predicted $y(t)$ 's. This function can be used for either out-of-sample predictions or for in-sample predictions if the "new" subjects are the same as the ones used to obtain the fitted NVC model.

## Usage

NVC_predict(NVC_mod, t_new, id_new, X_new)

## Arguments

NVC_mod an object with a fitted NVC model returned by the NVC_SSL or NVC_frequentist function
t_new vector of new observation times
id_new vector of new labels, where a label corresponds to one of the new subjects
X_new new design matrix with columns $\left[X_{1}, \ldots, X_{p}\right]$ where the $k$ th column corresponds to the $k$ th covariate. X_new must have the $p$ columns, i.e. the same number of varying coefficients estimated by NVC_mod.

## Value

The function returns a list containing the following components:

| id | vector of each $i$ th subject's label |
| :--- | :--- |
| time | vector of each $j$ th observation time for each $i$ th subject |
| y_pred | vector of predicted responses corresponding to each $j$ th observation time for <br> each $i$ th subject |

## Observation times
NVC_SSL_predictions$time
## Predicted responses
NVC_SSL_predictions$y_pred
```

NVC_SSL Nonparametric Varying Coefficient Spike-and-Slab Lasso (NVC-SSL)

## Description

This function implements the Nonparametric Varying Coefficient Spike-and-Slab Lasso (NVCSSL) model of Bai et al. (2023) for high-dimensional NVC models. The function returns the MAP estimator for the varying coefficients $\beta_{k}(t), k=1, \ldots, p$, obtained from the ECM algorithm described in Bai et al. (2023). The BIC criterion is used to select the optimal spike hyperparameter lambda ${ }_{0}$.

If the user specifies return_CI=TRUE, then this function will also return the 95 percent pointwise posterior credible intervals for the varying coefficients $\beta_{k}(t), k=1, \ldots, p$, obtained from Gibbs
sampling. If the number of covariates $p$ is large, then the user can additionally use the approximate MCMC algorithm introduced in Bai et al. (2023) (approx_MCMC=TRUE) which is much faster than the exact Gibbs sampler and gives higher simultaneous coverage.
Finally, this function returns the number of iterations and the runtime for the ECM algorithms and MCMC algorithms which can be used for benchmarking and timing comparisons.

## Usage

```
NVC_SSL(y, t, id, X, n_basis=8,
            lambda0=seq(from=300,to=10,by=-10), lambda1=1,
            a=1, b=ncol(X), c0=1, d0=1, nu=n_basis+2, Phi=diag(n_basis),
            include_intercept=TRUE, tol=1e-6, max_iter=100,
            return_CI=FALSE, approx_MCMC=FALSE,
            n_samples=1500, burn=500, print_iter=TRUE)
```

## Arguments

y $\quad N \times 1$ vector of response observations $y_{11}, \ldots, y_{1 m_{1}}, \ldots, y_{n 1}, \ldots, y_{n m_{n}}$
$\mathrm{t} \quad N \times 1$ vector of observation times $t_{11}, \ldots, t_{1 m_{1}}, \ldots, t_{n 1}, \ldots, t_{n m_{n}}$
id $\quad N \times 1$ vector of labels, where each unique label corresponds to one of the subjects
X $\quad N \times p$ design matrix with columns $\left[X_{1}, \ldots, X_{p}\right]$, where the $k$ th column contains the entries $x_{i k}\left(t_{i j}\right)$ 's
n_basis number of basis functions to use. Default is $n \_$basis=8.
lambda0 grid of spike hyperparameters. Default is to tune lambda0 from the grid of decreasing values $(300,290, \ldots, 20,10)$.
lambda1 slab hyperparameter. Default is lambda1=1.
a hyperparameter in $B(a, b)$ prior on mixing proportion $\theta$. Default is $a=1$.
b hyperparameter in $B(a, b)$ prior on mixing proportion $\theta$. Default is $b=p$.
c0 hyperparameter in Inverse-Gamma $\left(c_{0} / 2, d_{0} / 2\right)$ prior on measurement error variance $\sigma^{2}$. Default is $c_{0}=1$.
d0 hyperparameter in Inverse-Gamma $\left(c_{0} / 2, d_{0} / 2\right)$ prior on measurement error variance $\sigma^{2}$. Default is $d_{0}=1$.
nu degrees of freedom for Inverse-Wishart prior on $\Omega$. Default is $n \_b a s i s+2$.
Phi scale matrix in the Inverse-Wishart prior on $\Omega$. Default is the identity matrix.
include_intercept
Boolean variable for whether or not to include an intercept function $\beta_{0}(t)$ in the estimation. Default is include_intercept=TRUE.
tol convergence criteria for the ECM algorithm. Default is tol=1e-6.
max_iter maximum number of iterations to run ECM algorithm. Default is max_iter=100.
return_CI Boolean variable for whether or not to return the 95 percent pointwise credible bands. Set return_CI=TRUE if posterior credible bands are desired.

| approx_MCMC | Boolean variable for whether or not to run the approximate MCMC algorithm <br> instead of the exact MCMC algorithm. If approx_MCMC=TRUE, then an approx- <br> imate MCMC algorithm isused. Otherwise, if approx_MCMC=FALSE, the exact <br> MCMC algorithm is used. This argument is ignored if return_CI=FALSE. |
| :--- | :--- |
| n_samples | number of MCMC samples to save for posterior inference. The default is to save <br> n_samples=1500. This is ignored if return_CI=FALSE. |
| burn | number of initial MCMC samples to discard during the warm-up period. Default <br> is burn=500. This is ignored if return_CI=FALSE. |
| print_iter | Boolean variable for whether or not to print the progress of the algorithms. De- <br> fault is print_iter=TRUE. |

## Value

The function returns a list containing the following components:
t_ordered all $N$ time points ordered from smallest to largest. Needed for plotting classifications
$p \times 1$ vector of indicator variables, where " 1 " indicates that the covariate is selected and " 0 " indicates that it is not selected. These classifications are determined by the optimal lambda0 chosen from BIC. Note that this vector does not include an intercept function.
beta_hat $\quad N \times p$ matrix of the MAP estimates for varying coefficient functions $\beta_{k}(t), k=$ $1, \ldots, p$, using the optimal lambda0 chosen from BIC. The $k$ th column in the matrix is the $k$ th estimated function at the observation times in $t_{\text {_ordered. }}$
beta0_hat MAP estimate of the intercept function $\beta_{0}(t)$ at the observation times in t _ordered for the optimal lambda0 chosen from BIC. This is not returned if include_intercept = FALSE.
gamma_hat MAP estimates of the basis coefficients (needed for prediction) for the optimal lambda0.
beta_post_mean $N \times p$ matrix of the posterior mean estimates of the varying coefficient functions. The $k$ th column in the matrix is the $k$ th posterior mean estimate for $\beta_{k}(t)$ at the observation times in t_ordered. This is not returned if return_CI=FALSE.
beta_CI_lower $N \times p$ matrix of the lower endpoints of the 95 percent pointwise posterior credible interval (CI) for the varying coefficient functions. The $k$ th column in the matrix is the lower endpoint for the CI of $\beta_{k}(t)$ at the observation times in $t \_o r d e r e d$. This is not returned if return_CI=FALSE.
beta_CI_upper $\quad N \times p$ matrix of the upper endpoints of the 95 percent pointwise posterior credible interval (CI) for the varying coefficient functions. The $k$ th column in the matrix is the upper endpoint for the CI of $\beta_{k}(t)$ at the observation times in $t_{-}$ordered. This is not returned if return_CI=FALSE.
beta0_post_mean
Posterior mean estimate of the intercept function $\beta_{0}(t)$ at the observation times in $t_{-}$ordered. This is not returned if return_CI=FALSE.
beta0_CI_lower Lower endpoints of the 95 percent pointwise posterior credible intervals (CIs) for the intercept function $\beta_{0}(t)$ at the observation times in $t \_o r d e r e d$. This is not returned if return_CI=FALSE.
beta0_CI_upper Upper endpoints of the 95 percent pointwise posterior credible intervals (CIs) for the intercept function $\beta_{0}(t)$ at the observation times in $t \_o r d e r e d$. This is not returned if return_CI=FALSE.
gamma_post_mean
Posterior mean estimates of all the basis coefficients. This is not returned if return_CI=FALSE.
gamma_CI_lower Lower endpoints of the 95 percent posterior credible intervals for the basis coefficients. This is not returned if return_CI=FALSE.
gamma_CI_upper Upper endpoints of the 95 percent posterior credible intervals for the basis coefficients. This is not returned if return_CI=FALSE.
post_incl $\quad p \times 1$ vector of estimated posterior inclusion probabilities (PIPs) for each of the varying coefficients. The $k$ th entry in post_incl is the PIP for $\beta_{k}$. This is not returned if return_CI=FALSE.
lambda0_min the individual lambda0 which minimizes the BIC. If only one value was originally passed for lambda0, then this just returns that lambda0.
lambda0_all grid of all $L$ regularization parameters in lambda0. Note that since the objective function is scaled by $1 / N$ for the penalized frequentist methods in the NVC_frequentist function, the lambda_all grid that is chosen automatically by NVC_frequentist typically consists of smaller values than the default values in the lambda0_all grid for NVC_SSL.
BIC_all $L \times 1$ vector of BIC values corresponding to all $L$ entries in lambda0_all. The $l$ th entry corresponds to the $l$ th entry in lambda0_all.
beta_est_all_lambda0
list of length $L$ of the estimated varying coefficients $\beta_{k}(t), k=1, \ldots, p$, corresponding to all $L$ lambdas in lambda0_all. The $l$ th entry corresponds to the $l$ th entry in lambda0_all.
beta0_est_all_lambda0
$N \times L$ matrix of estimated intercept function $\beta_{0}(t)$ corresponding to all $L$ entries in lambda0_all. The lth column corresponds to the lth entry in lambda0_all. This is not returned if include_intercept=FALSE.
gamma_est_all_lambda0
$d p \times L$ matrix of estimated basis coefficients corresponding to all entries in lambda0_all. The $l$ th column corresponds to the $l$ th entry in lambda0_all.
classifications_all_lambda0
$p \times L$ matrix of classifications corresponding to all the entries in lambda0_all. The $l$ th column corresponds to the $l$ th entry in lambda0_all.
ECM_iters_to_converge
number of iterations it took for the ECM algorithm to converge for each entry in lambda0_all. The $l$ th entry corresponds to the $l$ th entry in lambda0_all.

ECM_runtimes $\quad L \times 1$ vector of the number of seconds it took for the ECM algorithm to converge for each entry in lambda0_all. The $l$ th entry corresponds to the $l$ th entry in lambda0_all.
gibbs_runtime number of minutes it took for the Gibbs sampling algorithm to run for the total number of MCMC iterations given in gibbs_iters
gibbs_iters total number of MCMC iterations run for posterior inference

SimulatedData Simulated data for illustration

## Description

This is a simulated dataset for illustration. It contains a total of $N=436$ observations at irregularly spaced time points for $n=50$ subjects. There are $p=100$ covariates.

## Usage <br> data(SimulatedData)

## Details

This simulated dataset contains $N=436$ observations for $n=50$ subjects, with $p=100$ covariates. The first column $y$ gives the response variables, the second column $t$ gives the observation times, the third column id gives the unique IDs for each of the 50 subjects, and columns 4-103 (x1, $\ldots, \mathrm{x} 100$ ) give the covariate values.
This synthetic dataset is a slight modification from Experiment 2 in Section 5.1 of Bai et al. (2023). We use $p=100$ for illustration, instead of $p=500$ as in the paper.
