Support Functions and Data for "Ecological Models and Data"

Description

Auxiliary functions and data sets for "Ecological Models and Data", a book presenting maximum likelihood estimation and related topics for ecologists (ISBN 978-0-691-12522-0).

References

Bolker, Benjamin M. Ecological Models and Data in R. Princeton University Press, 2008

`apply2d`*Apply a function to a combination of vectors*

Description

applies a (non-vectorized) function to a combination of vectors; substitute for `outer`

Usage

```
apply2d(fun, x, y, ..., use_plyr = TRUE, .progress="none")
```

Arguments

<code>fun</code>	a function of two arguments (or a character string such as <code>"*"</code>)
<code>x</code>	first vector
<code>y</code>	second vector
<code>...</code>	additional arguments to <code>fun</code>
<code>use_plyr</code>	use methods from the <code>plyr</code> package?
<code>.progress</code>	progress bar type (<code>"none"</code> , <code>"text"</code> , <code>"tk"</code> , <code>"win"</code> : see create_progress_bar)

Value

a matrix of the function applied to the combinations of the vector values

Author(s)

Ben Bolker

See Also

`outer`

Examples

```
outer(1:3,1:3)
## this example would work with outer() too
apply2d("*",1:3,1:3)
```

 as.mcmc.bugs

Convert WinBUGS output to CODA format

Description

Converts results of a bugs run (class "bugs") to a form that can be used by CODA (class "mcmc")

Usage

```
as.mcmc.bugs(x)
```

Arguments

x an object of class bugs (output from bugs())

Value

an object of class mcmc

Author(s)

Ben Bolker

 calcslice

Negative log-likelihood slice

Description

Calculate the negative log-likelihood along a line connecting two mle fits

Usage

```
calcslice(fit1, fit2, fn = fit1@minuslogl, range = c(-0.1, 1.1), n = 400)
```

Arguments

fit1 An mle object
 fit2 Another mle object
 fn Negative log-likelihood function
 range Numeric vector: range of parameters to try, where 0 corresponds to coef(fit1)
 and 1 corresponds to coef(fit2)
 n Number of points to evaluate

Details

Calculates the negative log-likelihood (not a profile, just a "slice") along the line connecting the two sets of coefficients. Intended for diagnosing and visualizing multiple minima in a likelihood surface, especially in higher-dimensional models.

Value

x	Parameter values, along the 0-1 scale described above
y	Negative log-likelihood values

Author(s)

Ben Bolker

contour3d

Superimpose contour lines on a 3D plot

Description

Plot contour lines computed from data in 3D, or add them to an existing 3D (RGL) surface

Usage

```
contour3d(x, y, z, contourArgs=NULL, ...)
```

Arguments

x	numeric vector of x values (as in contour), or a list with components x, y and z
y	numeric vector of y values (as in contour)
z	numeric z matrix (as in contour)
contourArgs	list of arguments to contourLines
...	other arguments to lines3d

Value

Returns a list of contour lines (as in [contourLines](#)), invisibly.

Note

You have to install the `rgl` package before you can use this function.

Note

If you are superimposing the contour lines on a surface, it helps to draw the surface with some level of transparency (alpha parameter: see [material3d](#)) so the contour lines are not obscured by the surface.

Author(s)

Ben Bolker

credint

*Calculate Bayesian credible intervals***Description**

Calculate Bayesian credible intervals based on various types of information about the posterior distribution

Usage

```
tcredint(dist, parlist, ranges, level = 0.95, eps = 1e-05, verbose=FALSE)
ncredint(pvec, npost, level=0.95, tol=0.01, verbose=FALSE)
```

Arguments

dist	character string giving the name of a distribution for which "d", "q", and "p" function exist, e.g. "beta"
parlist	list of parameters to pass to distribution functions
ranges	lower, middle, and upper values to bracket lower and upper boundaries of the credible interval
level	confidence level
eps	if ranges is missing, set lower and upper brackets to the eps and 1-eps quantiles of the distribution
tol	tolerance on credible interval
verbose	if TRUE, return detailed information on the probability cutoff and realized area of the credible interval; if FALSE, just lower and upper bounds of the credible region
pvec	numeric vector of parameter values
npost	numeric vector of posterior density values corresponding to pvec

Details

tcredint gives credible intervals for a theoretical posterior density with defined density, cumulative density, and quantile functions; ncredint gives credible intervals for a numerical posterior density.

Value

A numeric vector giving the credible interval. If verbose=FALSE, gives just lower and upper bounds; if verbose=TRUE, also gives information on the probability cutoff and realized area of the credible interval

Note

For credible intervals from a sample (e.g. from an MCMC run), see `HPDinterval` in the `coda` package.

Author(s)

Ben Bolker

Examples

```
tcredint("beta",list(shape1=5,shape2=10),verbose=TRUE)
pvec = seq(0,1,length=100)
postvec = dbeta(pvec,shape1=5,shape2=10)
ncredint(pvec,postvec,verbose=TRUE)
set.seed(1001)
```

curve3d

Plot a 3D surface representing a 2D curve

Description

Two-dimensional analogue of `curve`: generates a surface and plots it

Usage

```
curve3d(expr, from = c(0, 0), to = c(1, 1), n = c(41, 41),
        xlim, ylim, add = FALSE,
        xlab=varnames[1],
        ylab=varnames[2],
        zlab = NULL, log = NULL, sys3d = c("persp", "wireframe", "rgl",
        "contour", "image", "none"),
        varnames=c("x", "y"), use_plyr=TRUE, .progress="none", ...)
```

Arguments

<code>expr</code>	a mathematical expression using <code>x</code> and <code>y</code> as the independent variables
<code>from</code>	minimum values for <code>x</code> and <code>y</code>
<code>to</code>	maximum values for <code>x</code> and <code>y</code>
<code>xlim</code>	range of values for <code>x</code>
<code>ylim</code>	range of values for <code>y</code>
<code>n</code>	number of grid points in each direction
<code>add</code>	(logical) add to an existing plot? (only possible for contour plots or <code>rgl</code>)
<code>xlab</code>	<code>x</code> label
<code>ylab</code>	<code>y</code> label
<code>zlab</code>	<code>z</code> label

log	(character): "x", "y", or "xy" for logarithmic axes
sys3d	3D plotting system to use: one of "persp", "wireframe", "rgl", "contour", "image", or "none"
varnames	names of variables to substitute
use_plyr	use methods from the plyr package?
.progress	progress bar type ("none", "text", "tk", "win": see create_progress_bar)
...	additional arguments to the plotting functions

Value

invisibly, a list of

x	x values
y	y values
z	z matrix

Note

- You must explicitly install the rgl package (via `install.packages("rgl")`) before using `sys3d="persp"`.
- if you encounter the error ‘Results must have one or more dimensions’, try `use_plyr=FALSE` or use `c()` to remove attributes from the result of your expression

  varnames=c("a","b"))
curve3d(cos(2*pi*x)+sin(2*pi*y/3),
```

```
from=c(0,0),to=c(1,1),sys3d="image")
curve3d(cos(2*pi*x)+sin(2*pi*y/3),
        sys3d="contour",add=TRUE)
par(op)
```

Damselfish

Reef fish (damselfish) data

Description

Two data sets on *Dascyllus trimaculatus* (three-spot damselfish), one on the distribution of settlement densities to empty anemones across time and space, the other on survival (recruitment) of arriving settlers as a function of experimentally manipulated densities from Schmitt et al. (1999).

Usage

```
data(DamselSettlement)
data(DamselRecruitment)
data(DamselRecruitment_sum)
```

Format

Three data frames:

site settlement site (location)

pulse monthly settlement pulse

obs observation within pulse

density density of settlers per 0.1 m² anemone

area anemone area in cm²

init initial settler density

surv surviving density after 6 months

settler.den target experimental density of settlers on experimental anemones

surv.den mean surviving density after 6 months, by target density

SE standard error of survivor density, by target density

DOI: 10.1046/j.1461-0248.1999.00086.x (Original data kindly provided by Schmitt and Holbrook.) The original version of this data set is available from the [Moorea Coral Reef LTER data repository](#).

 dbetabinom

Beta-binomial distribution

Description

Density function and random variate generator for the beta-binomial function, parameterized in terms of probability and overdispersion

Usage

```
dbetabinom(x, prob, size, theta, shape1, shape2, log = FALSE)
rbetabinom(n, prob, size, theta, shape1, shape2)
```

Arguments

x	a numeric vector of integer values
prob	numeric vector: mean probability of underlying beta distribution
size	integer: number of samples
theta	overdispersion parameter
shape1	shape parameter of per-trial probability distribution
shape2	shape parameter of per-trial probability distribution
log	(logical) return log probability density?
n	integer number of random variates to return

Details

The beta-binomial distribution is the result of compounding a beta distribution of probabilities with a binomial sampling process. The density function is

$$p(x) = \frac{C(N, x) \text{Beta}(x + \theta p, N - x + \theta(1 - p))}{\text{Beta}(\theta p, \theta(1 - p))}$$

The parameters shape1 and shape2 are the more traditional parameterization in terms of the parameters of the per-trial probability distribution.

Value

A vector of probability densities or random deviates. If x is non-integer, the result is zero (and a warning is given).

Note

Although the quantile (qbetabinom) and cumulative distribution (pbetabinom) functions are not available, in a pinch they could be computed from the pghyper and qghyper functions in the SuppDists package – provided that shape2 > 1. As described in ?pghyper, pghyper(q, a = -shape1, N = -shape1 - shape2, k = size) should give the cumulative distribution for the beta-binomial distribution with parameters (shape1, shape2, size), and similarly for qghyper. (Translation to the (theta, size, prob) parameterization is left as an exercise.)

Examples

```
set.seed(100)
n <- 9
z <- rbetabinom(1000, 0.5, size=n, theta=4)
par(las=1,bty="l")
plot(table(z)/length(z),ylim=c(0,0.34),col="gray",lwd=4,
      ylab="probability")
points(0:n,dbinom(0:n,size=n,prob=0.5),col=2,pch=16,type="b")
points(0:n,dbetabinom(0:n,size=n,theta=4,
                     prob=0.5),col=4,pch=17,type="b")
## correspondence with SuppDists
if (require(SuppDists)) {
  d1a <- dghyper(0:5,a=-5,N=-10,k=5)
  d1b <- dbetabinom(0:5,shape1=5,shape2=5,size=5)
  max(abs(d1a-d1b))
  p1a <- pghyper(0:5,a=-5,N=-10,k=5,lower.tail=TRUE)
  p1b <- cumsum(d1b)
  max(abs(p1a-p1b))
}
```

dchibarsq

Mixed chi-squared distributions

Description

Calculates "mixed" chi-squared distributions (mixtures of chi-square(n) and chi-square(n-1)); useful for Likelihood Ratio Tests when parameters are on the boundary

Usage

```
dchibarsq(x, df = 1, mix = 0.5, log = FALSE)
pchibarsq(p, df = 1, mix = 0.5, lower.tail=TRUE, log.p = FALSE)
qchibarsq(q, df = 1, mix = 0.5)
rchibarsq(n, df = 1, mix = 0.5)
```

Arguments

x	numeric vector of positive values
p	numeric vector of positive values
q	numeric vector of quantiles (0-1)
n	integer: number of random deviates to pick
df	degrees of freedom (positive integer)
mix	mixture parameter: fraction of distribution that is chi-square(n-1) distributed
log	return log densities?
log.p	return log probabilities?
lower.tail	return lower tail values?

Value

Vectors of probability densities (dchibarsq), cumulative probabilities (pchibarsq), quantiles (qchibarsq), or random deviates (rchibarsq) from Goldman and Whelan's "chi-bar-squared" distribution. qchibarsq uses simple algebra for df=1 and [uniroot](#) for df>1.

Lee (1994) "Variance Components Testing in the Longitudinal Fixed Effects Model", *Biometrics* 50:1171-1177.

Examples

```
x <- rchibarsq(100)
plot(density(x, from=0))
curve(dchibarsq(x), add=TRUE, col=2, from=0)
## Not run:
library(lattice)
print(qqmath(~ simdist,
  distribution=qchibarsq,
  panel = function(x, ...) {
    panel.qqmathline(x, ...)
    panel.qqmath(x, ...)
  })))

## End(Not run)
## create first line of table in Goldman and Whelan 2000
round(qchibarsq(c(0.01,0.05,0.9,0.95,0.975,0.99,0.995),df=1),2)
## check second line of table
round(pchibarsq(c(3.81,5.14,6.48,8.27,9.63),df=2),3)
```

```
## create middle column
round(qchibarsq(0.95,df=1:10))
```

deltamethod *Delta method functions*

Description

Delta-method implementations for Jensen's inequality and prediction uncertainty

Usage

```
deltamethod(fun, z, var = "x", params = NULL, max.order = 2)
deltavar(fun, meanval=NULL, vars, Sigma, verbose=FALSE)
```

Arguments

fun	Function of one (deltamethod) or more arguments, expressed in raw form (e.g. $a*x/(b+x)$)
z	numeric vector of values
var	variable name
vars	list of variable names: needed if params does not have names, or if some of the values specified in params should be treated as constant
params	list or numeric vector of parameter values to substitute
meanval	possibly named vector of mean values of parameters
Sigma	numeric vector of variances or variance-covariance matrix
max.order	maximum order of delta method to compute
verbose	print details?

Details

deltamethod() is for computing delta-method approximations of the mean of a function of data; deltavar() is for estimating variances of a function based on the mean values and variance-covariance matrix of the parameters. If Sigma is a vector rather than a matrix, the parameters are assumed to be independently estimated.

Value

For deltavar(), a vector of predicted variances; for deltamethod() a vector containing the observed value of the function average, the function applied to the average, and a series of delta-method approximations

Author(s)

Ben Bolker

References

Lyons (1991), "A practical guide to data analysis for physical science students", Cambridge University Press

Examples

```
deltamethod(a*x/(b+x),runif(50),params=list(a=1,b=1),max.order=9)
deltavar(scale*gamma(1+1/shape),meanval=c(scale=0.8,shape=12),
  Sigma=matrix(c(0.015,0.125,0.125,8.97),nrow=2))
## more complex deltavar example
xvec = seq(-4,4,length=101)
x1 = xvec
x2 = xvec
v = matrix(0.2,nrow=3,ncol=3)
diag(v) = 1
m = c(b0=1,b1=1.5,b2=1)
v3 = deltavar(1/(1+exp(-(b0+b1*x1+b2*x2))),meanval=m,Sigma=v)
plot(xvec,v3)
```

 deprecated

Deprecated (obsolete) functions

Description

Functions that are obsolete for one reason or another

Author(s)

Ben Bolker

 dmvnorm

Multivariate normal distribution density function

Description

Calculates the probability density function of the multivariate normal distribution

Usage

```
dmvnorm(x, mu, Sigma, log = FALSE, tol = 1e-06)
```

Arguments

x	a vector or matrix of multivariate observations
mu	a vector or matrix of mean values
Sigma	a square variance-covariance matrix
log	(logical) return log-likelihood?
tol	tolerance for positive definiteness

Details

uses naive linear algebra – could probably use QR decomposition and/or crossprod.

Value

vector of log-likelihoods

Author(s)

Ben Bolker

See Also

[mvnorm](#) (in MASS package), [dmvnorm](#) (in mvtnorm package)

Examples

```
M = matrix(c(1,0.5,0.5,0.5,1,0.5,0.5,0.5,1),nrow=3)
dmvnorm(1:3,mu=1:3,Sigma=M,log=TRUE)
dmvnorm(matrix(1:6,nrow=2),mu=1:3,Sigma=M,log=TRUE)
dmvnorm(matrix(1:6,nrow=2),mu=matrix(1:6,nrow=2),Sigma=M,log=TRUE)
```

 dzinbinom

Zero-inflated negative binomial distribution

Description

Probability distribution function and random variate generation for the zero-inflated negative binomial distribution

Usage

```
dzinbinom(x, mu, size, zprob, log=FALSE)
rzinbinom(n, mu, size, zprob)
```

Arguments

x	vector of integer values
n	number of values to draw
mu	mean parameter (or vector of parameters) of negative binomial
size	number of trials/overdispersion parameter (or vector of parameters) of negative binomial
zprob	probability of structural zeros
log	return log probability?

Details

The zero-inflated negative binomial distribution is widely used to model extra zero counts in count data that otherwise follows a negative binomial distribution. The probability distribution is

$$p(0) = p_z + (1 - p_z)NB(0, \mu, k)$$

and

$$p(x) = (1 - p_z)NB(x, \mu, k)$$

for $x > 0$.

Value

Probabilities of x or random deviates.

Note

Only the "ecological" parameterization is included here (must specify mu, not prob)

GobySurvival

Goby (reef fish) survivorship data

Description

Survivorship data from experimental manipulations on gobies *Elacatinus evelynae* and *E. prochilos* in the US Virgin Islands, 2000-2002

Format

exper experiment
year year
site site (factor: backreef, patchreef)
head coral head (factor)
density treatment "density" (number of "target" fish)
qual treatment "quality"; background settlement rate
d1 last day observed (starting at 1)
d2 first day not observed

Details

These data have been made available by the author for pedagogical use; out of courtesy, please don't redistribute (outside of the context of this package) or use in an academic publication without requesting permission (via the package maintainer).

gg <- transform(GobySurvival,mid=(d1+d2)/2)  
plot(table(gg$mid))
```

`gridsearch2d`*Graphical grid search in 2D*

Description

Given an objective function and starting ranges, computes the values over the ranges and displays them in the graphics window. User can then interactively zoom in to view interesting parts of the surface.

Usage

```
gridsearch2d(fun, v1min, v2min, v1max, v2max,  
n1 = 20, n2 = 20, logz = FALSE,  
sys3d = c("both", "contour", "image"), ...)
```

Arguments

<code>fun</code>	Objective function to be minimized: function of two arguments
<code>v1min</code>	Minimum starting value of variable 1
<code>v2min</code>	Minimum starting value of variable 2
<code>v1max</code>	Maximum starting value of variable 1
<code>v2max</code>	Maximum starting value of variable 2
<code>n1</code>	Number of grid points for variable 1
<code>n2</code>	Number of grid points for variable 2
<code>logz</code>	Display image or contour on log scale?
<code>sys3d</code>	Display surface as an image, contour, or both?
<code>...</code>	Other arguments to fun

Details

If `log=TRUE`, the value of the surface is rescaled to $\log_{10}(m - \min(m) + \text{mindm})$, where `mindm` is the difference between the minimum and the next-largest value (or $1e-10$ if this difference is zero).

At each iteration, the user is prompted to select two corners of the new range with the mouse; if this choice is confirmed then the view zooms in. When the user chooses to quit, they are asked whether they want to choose a final point (e.g. an estimate of the minimum) with the mouse.

Value

If a final point is chosen, a list with elements `x` and `y`, otherwise `NULL`.

`HPDregionplot`*Plot highest posterior density region*

Description

Given a sample from a posterior distribution (an `mcmc` object from the `coda` package), plot the bivariate region of highest marginal posterior density for two variables, using `kde2d` from `MASS` to calculate a bivariate density.

Usage

```
HPDregionplot(x, vars = 1:2, h, n = 50, lump = TRUE, prob = 0.95, xlab =  
NULL, ylab = NULL, lims=NULL, ...)
```

Arguments

<code>x</code>	an <code>mcmc</code> or <code>mcmc.list</code> object
<code>vars</code>	which variables to plot: numeric or character vector
<code>h</code>	bandwidth of 2D kernel smoother (previous default value was <code>c(1,1)</code> , which worked poorly with some plots with very small scales; if not specified, defaults to values in kde2d)
<code>n</code>	number of points at which to evaluate the density grid
<code>lump</code>	if <code>x</code> is an <code>mcmc.list</code> object, lump the chains together for plotting?
<code>prob</code>	probability level
<code>xlab</code>	x axis label
<code>ylab</code>	y axis label
<code>lims</code>	limits, specified as <code>(x.lower,x.upper,y.lower,y.upper)</code> (passed to <code>kde2d</code>)
<code>...</code>	other arguments to contour

Details

Uses `kde2d` to calculate a bivariate density, then normalizes the plot and calculates the contour corresponding to a contained volume of `prob` of the total volume under the surface (a two-dimensional Bayesian credible region).

Value

Draws a plot on the current device, and invisibly returns a list of contour lines ([contourLines](#)).

Note

Accuracy may be limited by density estimation; you may need to tinker with `h` and `n` (see `kde2d` in the `MASS` package).

z2 <- mvrnorm(1000,mu=c(0,0),Sigma=matrix(c(2,1,1,2),nrow=2))
HPDregionplot(mcmc(z))
HPDregionplot(mcmc.list(mcmc(z),mcmc(z2)))
```

lambertW

*Lambert W function***Description**

Computes the Lambert W function, giving efficient solutions to the equation $x*\exp(x)=z$

Usage

```
lambertW_base(z, b = 0, maxiter = 10, eps = .Machine$double.eps, min.imag =
1e-09)
lWasymp(z, logz)
lambertW(z, ...)
```

Arguments

z	(complex) vector of values for which to compute the function
logz	(complex (?)) vector of $\log(z)$ values (to be specified by name instead of z)
b	(integer) b=0 specifies the principal branch, 0 and -1 are the ones that can take non-complex values
maxiter	maximum numbers of iterations for convergence
eps	convergence tolerance
min.imag	maximum magnitude of imaginary part to chop when returning solutions
...	arguments to pass to lambertW_base

Details

Compute the Lambert W function of z . This function satisfies $W(z) \exp(W(z)) = z$, and can thus be used to express solutions of transcendental equations involving exponentials or logarithms. For $z > 10^307$, an asymptotic formula (from Corless et al by way of <http://mathworld.wolfram.com/LambertW-Function.html>) is used: lambertW is a wrapper that automatically selects the asymptotic formula where appropriate.

- In ecology, the Lambert W can be used to solve the so-called "Rogers equation" for predator functional response with depletion.
- In epidemiology, the Lambert W function solves the final-size equation of a simple SIR epidemic model.

Value

Complex or real vector of solutions.

Note

This implementation should return values within $2.5 \cdot \text{eps}$ of its counterpart in Maple V, release 3 or later. Please report any discrepancies to the author or translator.

The derivative of the lambertW function is `plogis(-lambertW)`.

Lily

Glacier lily occurrence and fecundity data

Description

Data on sample quadrats of the glacier lily, *Erythronium grandiflorum*, from Thomson et al 1996

Usage

```
data(Lily_sum)
```

Format

```

x location of quadrat
y location of quadrat
flowers number of flowers

```

seedlings number of seedlings
 vegetative number of vegetative plants
 gopher index of gopher activity
 rockiness rockiness index
 moisture moisture index
 flowcol inverse quintile of flowering plants
 seedcol inverse quintile of seedlings
 vegcol inverse quintile of number of vegetative plants for image plots
 gophcol inverse quintile of gopher activity
 rockcol inverse quintile of rockiness
 moiscol inverse quintile of moisture

Details

16x16 grid of 2x2m quadrats in Washington Gulch, sampled 1992

Source

  image(matrix(Lily_sum[,i],nrow=16),main=names(Lily_sum)[i])
}
```

lseq	<i>Log-spaced sequence</i>
------	----------------------------

Description

Generates a logarithmically spaced sequence

Usage

```
lseq(from, to, length.out)
```

Arguments

from	starting value
to	ending value
length.out	number of intervening values

Details

lseq() is just a wrapper for `exp(seq(log(from), log(to), length.out = length.out))`

Value

logarithmically spaced sequence

coda package

metropSB

*Metropolis-Szymura-Barton algorithm***Description**

Stochastic global optimization using the Metropolis-Szymura-Barton algorithm. New parameters are chosen from a uniform candidate distribution with an adaptively tuned scale, and accepted or rejected according to a Metropolis rule.

Usage

```
metropSB(fn, start, deltap = NULL, scale = 1, rptfreq = -1, acceptscale
= 1.01, rejectscale = 0.99, nmax = 10000,
retvals = FALSE, retfreq = 100, verbose = FALSE, ...)
```

Arguments

fn	Objective function, taking a vector of parameters as its first argument. The function is minimized, so it should be a negative log-likelihood or a negative log-posterior density.
start	Vector of starting values
deltap	Starting jump size; half-width of uniform distribution
scale	Scaling factor for acceptance
rptfreq	Frequency for reporting interim results (<0 means no reporting)
acceptscale	Amount to inflate candidate distribution if last jump was accepted
rejectscale	Amount to shrink candidate distribution if last jump was rejected
nmax	Number of iterations
retvals	Return detailed statistics?
retfreq	Sampling frequency for detailed statistics
verbose	Print status?
...	Other arguments to fn

Details

Metropolis-Szymura-Barton algorithm: given function and starting value, try to find parameters that minimize the function Algorithm: at a given step, 1. pick a new set of parameters, each of which is uniformly distributed in $(p[i]-deltap[i], p[i]+deltap[i])$ 2. calculate function value at new parameter values 3. if $f(\text{new}) < f(\text{old})$, accept 4. if $f(\text{new}) > f(\text{old})$, accept with probability $(\exp(-scale * (f(\text{new}) - f(\text{old}))))$ 5. if accept, increase all deltap values by acceptscale; if reject, decrease by rejectscale 6. if better than min so far, save function and parameter values 7. if reject, restore old values

Value

minimum	minimum value achieved
estimate	parameters corresponding to minimum
funcalls	number of function evaluations
If retvals=TRUE:	
retvals	matrix of periodic samples including parameters, jump scale, current value, and minimum achieved value

Note

If scale=1 the algorithm satisfies MCMC rules, provided that the other properties of the MC (irreducibility and aperiodicity) are satisfied.

Myxo

Myxomatosis titer data

Description

Myxomatosis viral titer in blood samples from European rabbits, as a function of day-of-infection and virus grade, from Dwyer et al. 1990, ultimately from Fenner et al. 1956

Usage

```
data(MyxoTiter_sum)
```

Format

```
grade virus grade (1, least virulent; 5, most virulent)
day day of infection
titer blood virus titer (in log10 rabbit infectious doses)
```

Note

Pulled graphically from figure in Dwyer et al.; to be replaced (eventually) with original tabular data in Fenner et al.

Source

Dwyer, Levin and Buttel, "A Simulation Model of the Population Dynamics and Evolution of Myxomatosis", *Ecological Monographs* 60(4):423-447 (1990). Original source: Fenner et al. 1956

Examples

```
data(MyxoTiter_sum)
library(lattice)
xyplot(titer~day|factor(grade), data=MyxoTiter_sum, xlim=c(0, 30))
```

perturb.params	<i>Create a list of perturbed parameters</i>
----------------	--

Description

Takes a baseline set of parameters and perturbs it to create a variety of starting points for maximum likelihood estimation or MCMC

Usage

```
perturb.params(base, alt, which, mult = FALSE, use.base = TRUE)
```

Arguments

base	a named list (or vector) of parameters
alt	a list of lists (or vectors) of alternative parameter values or multipliers
which	which parameters to perturb (currently unused)
mult	(logical) multiply baseline values rather than replacing them?
use.base	(logical) include baseline parameters in the list?

Details

Takes the baseline parameter list and substitutes alternative values.

Value

A list of named lists of parameters.

Note

To be extended.

Author(s)

Ben Bolker

Examples

```
perturb.params(list(x=1,y=2,z=3),alt=list(x=c(2,4),z=5))
```

Reedfrog

*Data on reed frog predation experiments***Description**

Data on lab experiments on the density- and size-dependent predation rate of an African reed frog, *Hyperolius spinigularis*, from Vonesh and Bolker 2005

Usage

```
data(ReedfrogPred)
data(ReedfrogSizepred)
data(ReedfrogFuncresp)
```

Format

Various data with variables:

density initial tadpole density (number of tadpoles in a 1.2 x 0.8 x 0.4 m tank) [experiment 1]

pred factor: predators present or absent [experiment 1]

size factor: big or small tadpoles [experiment 1]

surv number surviving

propsurv proportion surviving (=surv/density) [experiment 1]

TBL tadpole body length in mm [size-predation experiment]

Kill number killed out of 10, in 3 days [size-predation]

Initial initial number/density (300 L tank) [functional response]

Killed number killed by 3 dragonfly larvae in 14 days [functional response]

Source

Vonesh and Bolker (2005) Compensatory larval responses shift trade-offs associated with predator-induced hatching plasticity. *Ecology* 86:1580-1591

Examples

```
data(ReedfrogPred)
boxplot(propsurv~size*density*pred,data=ReedfrogPred)
data(ReedfrogSizepred)
data(ReedfrogFuncresp)
```

scinot	<i>Scientific notation as LaTeX/expression()</i>
--------	--

Description

Takes a number and returns a version formatted in LaTeX (suitable for use with `Sexpr()` in an Sweave document) or in `expression()` (suitable for plotting), or plots an axis with labels in scientific notation

Usage

```
scinot(x, format = c("latex", "expression"), delim="$",
pref="", ...)
axis.scinot(side,at)
```

Arguments

<code>x</code>	a numeric vector (of length 1)
<code>format</code>	produce LaTeX or <code>expression()</code> format?
<code>delim</code>	delimiter to add at beginning and end (latex only)
<code>pref</code>	text to put before expression (expression only)
<code>side</code>	side on which to plot axis
<code>at</code>	list of locations/labels
<code>...</code>	additional arguments to <code>formatC</code>

Value

a character vector (if latex) or expression (if expression); `axis.scinot` draws an axis on the current plot

Author(s)

Ben Bolker

See Also

[formatC](#), [expression](#), [plotmath](#), [axis](#), [axTicks](#), `latexSN` in the `Hmisc` package, `eaxis` in the `sfsmisc` package

Examples

```
scinot(1e-5)
scinot(1e-5,digits=0)
scinot(1e-5,"expression")
scinot(1e-5,"expression",pref="p=")
set.seed(1001)
```

```
plot(1:100,rlnorm(100,0,2),log="y",axes=FALSE)
axis(side=1)
axis.scinot(side=2) ## fix bug!
```

SeedPred

Seed predation data set from Duncan and Duncan 2000

Description

Data on seed predation over time from Duncan and Duncan (2000)

Usage

```
data(SeedPred)
data(SeedPred_wide)
data(SeedPred_mass)
```

Format

station a factor specifying the station number
species a factor with levels abz cd cor dio mmu pol psd uva
date sample date
seeds number of seeds present
tcum cumulative time elapsed
tint time since last sample
taken seeds removed since last sample
dist distance from forest edge (m)

Details

SeedPred is in long format, SeedPred_wide is in wide format; SeedPred_wide has lots of NA values because stations at 10 and 25 m from the forest were sampled on different days. SeedPred_mass is a numeric vector containing the approximate seed masses for each species.

Source

R. Scot Duncan and Virginia E. Duncan (2000) Forest Succession and Distance from Forest Edge in an Afro-Tropical Grassland, *Biotropica* 32(1):33-41. (Data from Scot Duncan.)

Examples

```
data(SeedPred)
```

trcoef	<i>Transform coefficients</i>
--------	-------------------------------

Description

Perform standard transformations of coefficients based on information encoded in the names or the `transf` attribute of the vector or list

Usage

```
trcoef(x, inverse = FALSE)
```

Arguments

<code>x</code>	A numeric vector of coefficients with names and/or a <code>transf</code> attribute
<code>inverse</code>	(logical) Perform inverse transform?

Details

If `inverse=FALSE` and coefficient names begin with "logit", "log", or "sqrt" the function will back-transform them (using `plogis`, `exp`, or squaring), strip the descriptor from the names, and set the `transf` attribute. Naturally, `inverse=TRUE` will do the opposite. If the `transf` attribute is all empty strings after an inverse transformation, it will be deleted.

Value

A vector of transformed variables with modified names and `transf` attributes.

Author(s)

Ben Bolker

Examples

```
x = c(loga=1, logitb=2, sqrtc=2)
trx = trcoef(x); trx
trcoef(trx, inverse=TRUE)
```
