Title Tools for Quantitative Risk Management

Description Functions and data sets for reproducing selected results from the book “Quantitative Risk Management: Concepts, Techniques and Tools”. Furthermore, new developments and auxiliary functions for Quantitative Risk Management practice.

Author Marius Hofert [aut, cre],
Kurt Hornik [aut],
Alexander J. McNeil [aut]

Maintainer Marius Hofert <marius.hofert@uwaterloo.ca>

Depends R (>= 3.2.0)

Imports graphics, lattice, quantmod, Quandl, zoo, xts, methods,
grDevices, stats, rugarch, utils, ADGofTest

Suggests combinat, copula, qrng, sfsmisc, RColorBrewer, sn, knitr,
rmarkdown

alloc	<i>Computing allocations</i>
-------	------------------------------

Description

Computing (capital) allocations.

Usage

```
## For elliptical distributions under certain assumptions
alloc_ellip(total, loc, scale)

## Nonparametrically
conditioning(x, level, risk.measure = "VaR_np", ...)
alloc_np(x, level, risk.measure = "VaR_np", include.conditional = FALSE, ...)
```

Arguments

total	total to be allocated (typically the risk measure of the sum of the underlying loss random variables).
loc	location vector of the elliptical distribution of the loss random vector.
scale	scale (covariance) matrix of the elliptical distribution of the loss random vector.
x	(n, d) -matrix containing n iid d -dimensional losses.
level	either one or two confidence level(s) for <code>risk.measure</code> ; in the former case the upper bound on the conditioning region is determined by confidence level 1.
risk.measure	character string or function specifying the risk measure to be computed on the row sums of <code>x</code> based on the given level(s) in order to determine the conditioning region.
include.conditional	logical indicating whether the computed sub-sample of <code>x</code> is to be returned, too.
...	additional arguments passed to <code>risk.measure</code> .

Details

The result of `alloc_ellip()` for `loc = 0` can be found in McNeil et al. (2015, Corollary 8.43). Otherwise, McNeil et al. (2015, Theorem 8.28 (1)) can be used to derive the result.

Value

d -vector of allocated amounts (the allocation) according to the Euler principle under the assumption that the underlying loss random vector follows a d -dimensional elliptical distribution with location vector `loc` ($\boldsymbol{\mu}$ in the reference) and scale matrix `scale` (Σ in the reference, a covariance matrix) and that the risk measure is law-invariant, positive-homogeneous and translation invariant.

Author(s)

Marius Hofert

References

McNeil, A. J., Frey, R. and Embrechts, P. (2015). *Quantitative Risk Management: Concepts, Techniques, Tools*. Princeton University Press.

Examples

```
### Elliptical case #####

## Construct a covariance matrix
sig <- 1:3 # standard deviations
library(copula) # for p2P() here
P <- p2P(c(-0.5, 0.3, 0.5)) # (3, 3) correlation matrix
Sigma <- P * sig %*% t(sig) # corresponding covariance matrix
stopifnot(all.equal(cov2cor(Sigma), P)) # sanity check

## Compute the allocation of 1.2 for a joint loss  $L \sim E_3(0, \text{Sigma}, \text{psi})$ 
```

```

AC <- alloc_ellip(1.2, loc = 0, scale = Sigma) # allocated amounts
stopifnot(all.equal(sum(AC), 1.2)) # sanity check
## Be careful to check whether the aforementioned assumptions hold.

### Nonparametrically #####

## Generate data
set.seed(271)
X <- qt(rCopula(1e5, copula = gumbelCopula(2, dim = 5)), df = 3.5)

## Estimate an allocation via MC based on a sub-sample whose row sums have a
## nonparametric VaR with confidence level in ...
alloc_np(X, level = 0.9) # ... (0.9, 1]
CA <- alloc_np(X, level = c(0.9, 0.95)) # ... in (0.9, 0.95]
CA.< <- alloc_np(X, level = c(0.9, 0.95), risk.measure = VaR_np) # providing a function
stopifnot(identical(CA, CA.<))

```

Black_Scholes

Black–Scholes formula and the Greeks

Description

Compute the Black–Scholes formula and the Greeks.

Usage

```

Black_Scholes(t, S, r, sigma, K, T, type = c("call", "put"))
Black_Scholes_Greeks(t, S, r, sigma, K, T, type = c("call", "put"))

```

Arguments

t	initial or current time t (in years).
S	stock price at time t .
r	risk-free annual interest rate.
sigma	annual volatility (standard deviation).
K	strike.
T	maturity (in years).
type	character string indicating whether a call (the default) or a put option is considered.

Details

Note again that t is time in years. In the context of McNeil et al. (2015, Chapter 9), this is $\tau_t = t/250$.

Value

Black_Scholes() returns the value of a European-style call or put option (depending on the chosen type) on a non-dividend paying stock.

Black_Scholes_Greeks() returns the first-order derivatives delta, theta, rho, vega and the second-order derivatives gamma, vanna and vomma (depending on the chosen type) in this order.

Brownian

Brownian and Related Motions

Description

Simulate paths of dependent Brownian motions, geometric Brownian motions and Brownian bridges based on given increment copula samples. And extract copula increments from paths of dependent Brownian motions and geometric Brownian motions.

Usage

```
rBrownian(N, t, d = 1, U = matrix(runif(N * n * d), ncol = d),
          drift = 0, vola = 1, type = c("BM", "GBM", "BB"), init = 1)
deBrowning(x, t, drift = 0, vola = 1, type = c("BM", "GBM"))
```

Arguments

N	number N of paths to simulate (positive integer).
x	$n+1$ -vector containing one path of the specified stochastic process or $(n+1, d)$ -matrix containing one path of the specified d stochastic processes or $(N, n+1, d)$ -array containing N paths of the specified d stochastic processes.
t	$n+1$ -vector of the form (t_0, \dots, t_n) with $0 = t_0 < \dots < t_n$ containing the time points where the stochastic processes are considered.
d	number d of stochastic processes to simulate (positive integer).
U	$(N \cdot n, d)$ -matrix of copula realizations to be converted to the joint increments of the stochastic processes.
drift	d -vector or number (then recycled to a d -vector) of drifts (typically denoted by μ). Note that risk-neutral drifts are $r - \sigma^2/2$, where r is the risk-free interest rate and σ the volatility.

vola d -vector or number (then recycled to a d -vector) of volatilities (typically denoted by σ).

type **character** string indicating whether a Brownian motion ("BM"), geometric Brownian motion ("GBM") or Brownian bridge ("BB") is to be considered.

init d -vector or number (then recycled to a d -vector) of initial values (typically stock prices at time 0) for type = "GBM".

Value

`rBrownian()` returns an $(N, n + 1, d)$ -array containing the N paths of the specified d stochastic processes simulated at the $n + 1$ time points $(t_0 = 0, t_1, \dots, t_n)$.

`deBrowning()` returns an (N, n, d) -array containing the N paths of the copula increments of the d stochastic processes over the $n + 1$ time points $(t_0 = 0, t_1, \dots, t_n)$.

Author(s)

Marius Hofert

Examples

```
## Setup
d <- 3 # dimension
library(copula)
tcop <- tCopula(iTau(tCopula()), tau = 0.5), dim = d, df = 4) # t_4 copula
vola <- seq(0.05, 0.20, length.out = d) # volatilities sigma
r <- 0.01 # risk-free interest rate
drift <- r - vola^2/2 # marginal drifts
init <- seq(10, 100, length.out = d) # initial stock prices
N <- 100 # number of replications
n <- 25 # number of time intervals
t <- 0:n/n # time points 0 = t_0 < ... < t_n

## Simulate N paths of a cross-sectionally dependent d-dimensional
## (geometric) Brownian motion ((G)BM) over n time steps
set.seed(271)
U <- rCopula(N * n, copula = tcop) # for dependent increments
X <- rBrownian(N, t = t, d = d, U = U, drift = drift, vola = vola) # BM
S <- rBrownian(N, t = t, d = d, U = U, drift = drift, vola = vola,
               type = "GBM", init = init) # GBM
stopifnot(dim(X) == c(N, n+1, d), dim(S) == c(N, n+1, d))

## DeBrowning
Z.X <- deBrowning(X, t = t, drift = drift, vola = vola) # BM
Z.S <- deBrowning(S, t = t, drift = drift, vola = vola, type = "GBM") # GBM
stopifnot(dim(Z.X) == c(N, n, d), dim(Z.S) == c(N, n, d))
## Note that for BMs, one loses one observation as  $X_{\{t_0\}} = 0$  (or some other
## fixed value, so there is no random increment there that can be deBrowned.

## If we map the increments back to their copula sample, do we indeed
## see the copula samples again?
```

```

U.Z.X <- pnorm(Z.X) # map to copula sample
U.Z.S <- pnorm(Z.S) # map to copula sample
stopifnot(all.equal(U.Z.X, U.Z.S)) # sanity check
## Visual check
pairs(U.Z.X[,1,], gap = 0) # check at the first time point of the BM
pairs(U.Z.X[,n,], gap = 0) # check at the last time point of the BM
pairs(U.Z.S[,1,], gap = 0) # check at the first time point of the GBM
pairs(U.Z.S[,n,], gap = 0) # check at the last time point of the GBM
## Numerical check
## First convert the (N * n, d)-matrix U to an (N, n, d)-array but in
## the right way (array(U, dim = c(N, n, d)) would use the U's in the
## wrong order)
U. <- aperm(array(U, dim = c(n, N, d)), perm = c(2,1,3))
## Now compare
stopifnot(all.equal(U.Z.X, U., check.attributes = FALSE))
stopifnot(all.equal(U.Z.S, U., check.attributes = FALSE))

## Generate dependent GBM sample paths with quasi-random numbers
library(qrng)
set.seed(271)
U. <- cCopula(to_array(sobol(N, d = d * n, randomize = "digital.shift"), f = n),
             copula = tcop, inverse = TRUE)
S. <- rBrownian(N, t = t, d = d, U = U., drift = drift, vola = vola,
              type = "GBM", init = init)
pairs(S [,2,], gap = 0) # pseudo-samples at t_1
pairs(S.[,2,], gap = 0) # quasi-samples at t_1
pairs(S [,n+1,], gap = 0) # pseudo-samples at t_n
pairs(S.[,n+1,], gap = 0) # quasi-samples at t_n

## Generate paths from a Brownian bridge
B <- rBrownian(N, t = t, type = "BB")
plot(NA, xlim = 0:1, ylim = range(B),
     xlab = "Time t", ylab = expression("Brownian bridge path"~(B[t])))
for(i in 1:N)
  lines(t, B[i,,], col = adjustcolor("black", alpha.f = 25/N))

```

catch

Catching Results, Warnings and Errors Simultaneously

Description

Catches results, warnings and errors.

Usage

```
catch(expr)
```

Arguments

`expr` expression to be evaluated, typically a function call.

Details

This function is particularly useful for large(r) simulation studies to not fail until finished.

Value

`list` with components:

`value` value of `expr` or `NULL` in case of an error.
`warning` warning message (see `simpleWarning` or `warning()`) or `NULL` in case of no warning.
`error` error message (see `simpleError` or `stop()`) or `NULL` in case of no error.

Author(s)

Marius Hofert (based on `doCallWE()` and `tryCatch.W.E()` in the R package `simsalapar`).

Examples

```
catch(log(2))
catch(log(-1))
catch(log("a"))
```

fit_ARMA_GARCH

Fitting ARMA-GARCH Processes

Description

Fail-safe componentwise fitting of univariate ARMA-GARCH processes.

Usage

```
fit_ARMA_GARCH(x, ugarchspec.list = ugarchspec(), solver = "hybrid",
               verbose = FALSE, ...)
```

Arguments

`x` `matrix`-like data structure, possibly an `xts` object.
`ugarchspec.list` object of class `uGARCHspec` (as returned by `ugarchspec()`) or a list of such. In case of a list, its length has to be equal to the number of columns of `x`. `ugarchspec.list` provides the ARMA-GARCH specifications for each of the time series (columns of `x`).
`solver` string indicating the solver used; see `?ugarchfit`.
`verbose` `logical` indicating whether verbose output is given.
`...` additional arguments passed to the underlying `ugarchfit()`.

Value

If x consists of one column only (e.g. a vector), ARMA_GARCH() returns the fitted object; otherwise it returns a list of such.

Author(s)

Marius Hofert

fit_GARCH_11

Fast(er) and Numerically More Robust Fitting of GARCH(1,1) Processes

Description

Fast(er) and numerically more robust fitting of GARCH(1,1) processes according to Zumbach (2000).

Usage

```

fit_GARCH_11(x, init = NULL, sig2 = mean(x^2), delta = 1,
  distr = c("norm", "st"), control = list(), ...)
tail_index_GARCH_11(innovations, alpha1, beta1,
  interval = c(1e-6, 1e2), ...)

```

Arguments

<code>x</code>	vector of length n containing the data (typically log-returns) to be fitted a GARCH(1,1) to.
<code>init</code>	vector of length 2 giving the initial values for the likelihood fitting. Note that these are initial values for z_{corr} and z_{ema} as in Zumbach (2000).
<code>sig2</code>	annualized variance (third parameter of the reparameterization according to Zumbach (2000)).

delta	unit of time (defaults to 1 meaning daily data; for yearly data, use 250).
distr	character string specifying the innovation distribution ("norm" for N(0,1) or "st" for a standardized t distribution).
control	see <code>?optim()</code> .
innovations	random variates from the innovation distribution; for example, obtained via <code>rnorm()</code> or <code>rt(, df = nu) * sqrt((nu-2)/nu)</code> where <code>nu</code> are the d.o.f. of the t distribution.
alpha1	nonnegative GARCH(1,1) coefficient $alpha[1]$ satisfying $alpha[1] + beta[1] < 1$.
beta1	nonnegative GARCH(1,1) coefficient $beta[1]$ satisfying $alpha[1] + beta[1] < 1$.
interval	initial interval for computing the tail index; passed to the underlying <code>uniroot()</code> .
...	<code>fit_GARCH_11()</code> : additional arguments passed to the underlying <code>optim()</code> . <code>tail_index_GARCH_11()</code> : additional arguments passed to the underlying <code>uniroot()</code> .

Value

`fit_GARCH_11()`: **coef**: estimated coefficients $\alpha_0, \alpha_1, \beta_1$ and, if `distr = "st"` the estimated degrees of freedom.

logLik: maximized log-likelihood.

counts: number of calls to the objective function; see `?optim`.

convergence: convergence code ('0' indicates successful completion); see `?optim`.

message: see `?optim`.

sig.t: vector of length n giving the conditional volatility.

Z.t: vector of length n giving the standardized residuals.

`tail_index_GARCH_11()`: The tail index $alpha$ estimated by Monte Carlo via McNeil et al. (2015, p. 576), so the $alpha$ which solves

$$E((\alpha_1 Z^2 + \beta_1)^{\alpha/2}) = 1$$

, where Z are the innovations. If no solution is found (e.g. if the objective function does not have different sign at the endpoints of `interval`), `NA` is returned.

```

fit_GEV

Parameter Estimators of the Generalized Extreme Value Distribution

Description

Quantile matching estimator, probability weighted moments estimator, log-likelihood and maximum-likelihood estimator for the parameters of the generalized extreme value distribution (GEV).

Usage

```

fit_GEV_quantile(x, p = c(0.25, 0.5, 0.75), cutoff = 3)
fit_GEV_PWM(x)

logLik_GEV(param, x)
fit_GEV_MLE(x, init = c("shape0", "PWM", "quantile"),
            estimate.cov = TRUE, control = list(), ...)

```

Arguments

x numeric vector of data. In the block maxima method, these are the block maxima.

p numeric(3) specifying the probabilities whose quantiles are matched.

cutoff	positive z after which $\exp(-z)$ is truncated to 0.
param	numeric(3) containing the value of the shape ξ (a real), location μ (a real) and scale σ (positive real) parameters of the GEV distribution in this order.
init	character string specifying the method for computing initial values. Can also be numeric(3) for directly providing ξ, μ, σ .
estimate.cov	logical indicating whether the asymptotic covariance matrix of the parameter estimators is to be estimated (inverse of observed Fisher information (negative Hessian of log-likelihood evaluated at MLE)) and standard errors for the estimators of ξ, μ, σ returned, too.
control	list ; passed to the underlying <code>optim()</code> .
...	additional arguments passed to the underlying <code>optim()</code> .

Details

`fit_GEV_quantile()` matches the empirical p-quantiles.

`fit_GEV_PWM()` computes the probability weighted moments (PWM) estimator of Hosking et al. (1985); see also Landwehr and Wallis (1979).

`fit_GEV_MLE()` uses, as default, the case $\xi = 0$ for computing initial values; this is actually a small positive value since Nelder–Mead could fail otherwise. For the other available methods for computing initial values, σ (obtained from the case $\xi = 0$) is doubled in order to guarantee a finite log-likelihood at the initial values. After several experiments (see the source code), one can safely say that finding initial values for fitting GEVs via MLE is non-trivial; see also the block maxima method script about the Black Monday event on <https://qrmtutorial.org>.

Caution: See Coles (2001, p. 55) for how to interpret $\xi \leq -0.5$; in particular, the standard asymptotic properties of the MLE do not apply.

Value

`fit_GEV_quantile()` and `fit_GEV_PWM()` return a numeric(3) giving the parameter estimates for the GEV distribution.

`logLik_GEV()` computes the log-likelihood of the GEV distribution ($-\text{Inf}$ if not admissible).

`fit_GEV_MLE()` returns the return object of `optim()` (by default, the return value value is the log-likelihood) and, appended, the estimated asymptotic covariance matrix and standard errors of the parameter estimators, if `estimate.cov`.

})
plot(xi., pLL, type = "l", xlab = expression(xi),
      ylab = "GEV distribution profile log-likelihood")

```

fit_GPD

Parameter Estimators of the Generalized Pareto Distribution

Description

Method-of-moments estimator, probability weighted moments estimator, log-likelihood and maximum-likelihood estimator for the parameters of the generalized Pareto distribution (GPD).

Usage

```

fit_GPD_MOM(x)
fit_GPD_PWM(x)

logLik_GPD(param, x)
fit_GPD_MLE(x, init = c("PWM", "MOM", "shape0"),
            estimate.cov = TRUE, control = list(), ...)

```

Arguments

x	numeric vector of data. In the peaks-over-threshold method, these are the excesses (exceedances minus threshold).
param	numeric(2) containing the value of the shape ξ (a real) and scale β (positive real) parameters of the GPD in this order.
init	character string specifying the method for computing initial values. Can also be numeric(2) for directly providing ξ and β .
estimate.cov	logical indicating whether the asymptotic covariance matrix of the parameter estimators is to be estimated (inverse of observed Fisher information (negative Hessian of log-likelihood evaluated at MLE)) and standard errors for the estimators of ξ and β returned, too.
control	list ; passed to the underlying <code>optim()</code> .
...	additional arguments passed to the underlying <code>optim()</code> .

Details

`fit_GPD_MOM()` computes the method-of-moments (MOM) estimator.

`fit_GPD_PWM()` computes the probability weighted moments (PWM) estimator of Hosking and Wallis (1987); see also Landwehr et al. (1979).

`fit_GPD_MLE()` uses, as default, `fit_GPD_PWM()` for computing initial values. The former requires the data x to be non-negative and adjusts β if ξ is negative, so that the log-likelihood at the initial value should be finite.

Value

`fit_GEV_MOM()` and `fit_GEV_PWM()` return a `numeric(3)` giving the parameter estimates for the GPD.

`logLik_GPD()` computes the log-likelihood of the GPD ($-\text{Inf}$ if not admissible).

`fit_GPD_MLE()` returns the return object of `optim()` and, appended, the estimated asymptotic covariance matrix and standard errors of the parameter estimators, if `estimate.cov`.

logLik <- sapply(xi., function(xi..) logLik_GPD(c(xi.., beta), x = X))
plot(xi., logLik, type = "l", xlab = expression(xi),
     ylab = expression("GPD log-likelihood for fixed"~beta))

## Plot the profile likelihood for these xi's
## (with an initial interval for the nuisance parameter beta such that
## logLik_GPD() is finite)
pLL <- sapply(xi., function(xi..) {
  ## Choose beta interval for optimize()
  int <- if(xi.. >= 0) {
    ## Method-of-Moment estimator
    mu.hat <- mean(X)
    sig2.hat <- var(X)
    shape.hat <- (1-mu.hat^2/sig2.hat)/2
    scale.hat <- mu.hat*(1-shape.hat)
    ## log-likelihood always fine for xi.. >= 0 for all beta
    c(1e-8, 2 * scale.hat)
  } else { # xi.. < 0
    ## Make sure logLik_GPD() is finite at endpoints of int
    mx <- max(X)
    -xi.. * mx * c(1.01, 100) # -xi * max(X) * scaling
    ## Note: for shapes xi.. closer to 0, the upper scaling factor
    ##       needs to be chosen sufficiently large in order
    ##       for optimize() to find an optimum (not just the
    ##       upper end point). Try it with '2' instead of '100'.
  }
  ## Optimization
  optimize(function(nuis) logLik_GPD(c(xi.., nuis), x = X),
           interval = int, maximum = TRUE)$maximum
})
plot(xi., pLL, type = "l", xlab = expression(xi),
     ylab = "GPD profile log-likelihood")

```

Description

Download (and possibly) merge data from freely available databases.

Usage

```
get_data(x, from = NULL, to = NULL,
         src = c("yahoo", "quandl", "oanda", "FRED", "google"),
         FUN = NULL, verbose = TRUE, warn = TRUE, ...)
```

Arguments

x	vector of ticker symbols (e.g. "^GSPC" if src = "yahoo" or "EUR/USD" if src = "oanda").
from	start date as a Date object or character string (in international date format "yyyy-mm-dd"); if NULL, the earliest date with available data is picked.
to	end date as a Date object or character string (in international date format "yyyy-mm-dd"); if NULL, the last date with available data is picked.
src	character string specifying the data source (e.g. "yahoo" for stocks or "oanda" for FX data); see getSymbols() and Quandl() .
FUN	function to be applied to the data before being returned. This can be the identity: if the data could not be retrieved (and is thus replaced by NA); the given FUN: if FUN has been provided; a useful default: if FUN = NULL; the default uses the adjusted close price Ad() if src = "yahoo", the close price Cl() if src = "google" and the identity otherwise.
verbose	logical indicating whether progress monitoring should be done.
warn	logical indicating whether a warning is given showing the error message when fetching x fails.
...	additional arguments passed to the underlying getSymbols() from quantmod or Quandl() from Quandl (if src = "quandl").

Details

FUN is typically one of **quantmod**'s [Op](#), [Hi](#), [Lo](#), [Cl](#), [Vo](#), [Ad](#) or one of the combined functions [OpCl](#), [ClCl](#), [HiCl](#), [LoCl](#), [LoHi](#), [OpHi](#), [OpLo](#), [OpOp](#).

Value

xts object containing the data with column name(s) adjusted to be the ticker symbol (in case lengths match; otherwise the column names are not adjusted); [NA](#) if data is not available.

Author(s)

Marius Hofert

Examples

```
## Not run:
## Note: This needs a working internet connection
## Get stock and volatility data (for all available trading days)
dat <- get_data(c("^GSPC", "^VIX")) # note: this needs a working internet connection
```

```
## Plot them (Alternative: plot.xts() from xtsExtra)
library(zoo)
plot.zoo(dat, screens = 1, main = "", xlab = "Trading day", ylab = "Value")

## End(Not run)
```

 GEV

Generalized Extreme Value Distribution

Description

Density, distribution function, quantile function and random variate generation for the generalized extreme value distribution (GEV).

Usage

```
dGEV(x, shape, loc = 0, scale = 1, log = FALSE)
pGEV(q, shape, loc = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qGEV(p, shape, loc = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rGEV(n, shape, loc = 0, scale = 1)
```

Arguments

x, q	vector of quantiles.
p	vector of probabilities.
n	number of observations.
shape	GEV shape parameter ξ , a real.
loc	GEV location parameter μ , a real.
scale	GEV scale parameter σ , a positive real.
lower.tail	logical ; if TRUE (default) probabilities are $P(X \leq x)$ otherwise, $P(X > x)$.
log, log.p	logical ; if TRUE, probabilities p are given as $\log(p)$.

Details

The distribution function of the generalized extreme value distribution is given by

$$F(x) = \begin{cases} \exp(-(1 - \xi(x - \mu)/\sigma)^{-1/\xi}), & \xi \neq 0, 1 + \xi(x - \mu)/\sigma > 0, \\ \exp(-e^{-(x - \mu)/\sigma}), & \xi = 0, \end{cases}$$

where $\sigma > 0$.

Value

dGEV() computes the density, pGEV() the distribution function, qGEV() the quantile function and rGEV() random variates of the generalized extreme value distribution.

Author(s)

Marius Hofert

References

McNeil, A. J., Frey, R., and Embrechts, P. (2015). *Quantitative Risk Management: Concepts, Techniques, Tools*. Princeton University Press.

Examples

```
## Basic sanity checks
plot(pGEV(rGEV(1000, shape = 0.5), shape = 0.5)) # should be U[0,1]
curve(dGEV(x, shape = 0.5), from = -3, to = 5)
```

 GEV_shape_plot

Fitted GEV Shape as a Function of the Threshold

Description

Fit GEVs to block maxima and plot the fitted GPD shape as a function of the block size.

Usage

```
GEV_shape_plot(x, blocksize = tail(pretty(seq_len(length(x)/20), n = 64), -1),
  estimate.cov = TRUE, conf.level = 0.95,
  CI.col = adjustcolor(1, alpha.f = 0.2),
  lines.args = list(), xlim = NULL, ylim = NULL,
  xlab = "Block size", ylab = NULL,
  xlab2 = "Number of blocks", plot = TRUE, ...)
```

Arguments

<code>x</code>	<code>vector</code> of <code>numeric</code> data.
<code>blocksize</code>	<code>numeric</code> vector of block sizes for which to fit a GEV to the block maxima.
<code>estimate.cov</code>	<code>logical</code> indicating whether confidence intervals are to be computed.
<code>conf.level</code>	confidence level of the confidence intervals if <code>estimate.cov</code> .
<code>CI.col</code>	color of the pointwise asymptotic confidence intervals (CIs); if NA, no CIs are shown.
<code>lines.args</code>	<code>list</code> of arguments passed to the underlying <code>lines()</code> for drawing the shape parameter as a function of the block size.
<code>xlim, ylim, xlab, ylab</code>	see <code>plot()</code> .
<code>xlab2</code>	label of the secondary x-axis.
<code>plot</code>	<code>logical</code> indicating whether a plot is produced.
<code>...</code>	additional arguments passed to the underlying <code>plot()</code> .

Details

Such plots can be used in the block maxima method for determining the optimal block size (as the smallest after which the plot is (roughly) stable).

Value

Invisibly returns a `list` containing the block sizes considered, the corresponding block maxima and the fitted GEV distribution objects as returned by the underlying `fit_GEV_MLE()`.

Author(s)

Marius Hofert

Examples

```
set.seed(271)
X <- rPar(5e4, shape = 4)
GEV_shape_plot(X)
abline(h = 1/4, lty = 3) # theoretical xi = 1/shape for Pareto
```

GPD

(Generalized) Pareto Distribution

Description

Density, distribution function, quantile function and random variate generation for the (generalized) Pareto distribution (GPD).

Usage

```
dGPD(x, shape, scale, log = FALSE)
pGPD(q, shape, scale, lower.tail = TRUE, log.p = FALSE)
qGPD(p, shape, scale, lower.tail = TRUE, log.p = FALSE)
rGPD(n, shape, scale)

dPar(x, shape, scale = 1, log = FALSE)
pPar(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qPar(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rPar(n, shape, scale = 1)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations.
<code>shape</code>	GPD shape parameter ξ (a real number) and Pareto shape parameter θ (a positive number).

scale	GPD scale parameter β (a positive number) and Pareto scale parameter κ (a positive number).
lower.tail	logical ; if TRUE (default) probabilities are $P(X \leq x)$ otherwise, $P(X > x)$.
log, log.p	logical; if TRUE, probabilities p are given as $\log(p)$.

Details

The distribution function of the generalized Pareto distribution is given by

$$F(x) = \begin{cases} 1 - (1 + \xi x/\beta)^{-1/\xi}, & \xi \neq 0, \\ 1 - \exp(-x/\beta), & \xi = 0, \end{cases}$$

where $\beta > 0$ and $x \geq 0$ if $\xi \geq 0$ and $x \in [0, -\beta/\xi]$ if $\xi < 0$.

The distribution function of the Pareto distribution is given by

$$F(x) = 1 - (1 + x/\kappa)^{-\theta}, \quad x \geq 0,$$

where $\theta > 0, \kappa > 0$.

In contrast to `dGPD()`, `pGPD()`, `qGPD()` and `rGPD()`, the functions `dPar()`, `pPar()`, `qPar()` and `rPar()` are vectorized in their main argument and the parameters.

Value

`dGPD()` computes the density, `pGPD()` the distribution function, `qGPD()` the quantile function and `rGPD()` random variates of the generalized Pareto distribution.

Similarily for `dPar()`, `pPar()`, `qPar()` and `rPar()` for the Pareto distribution.

Author(s)

Marius Hofert

References

McNeil, A. J., Frey, R., and Embrechts, P. (2015). *Quantitative Risk Management: Concepts, Techniques, Tools*. Princeton University Press.

Examples

```
## Basic sanity checks
curve(dGPD(x, shape = 0.5, scale = 3), from = -1, to = 5)
plot(pGPD(rGPD(1000, shape = 0.5, scale = 3), shape = 0.5, scale = 3)) # should be U[0,1]
```

GPDtail

*GPD-Based Tail Distribution (POT method)***Description**

Density, distribution function, quantile function and random variate generation for the GPD-based tail distribution in the POT method.

Usage

```
dGPDtail(x, threshold, p.exceed, shape, scale, log = FALSE)
pGPDtail(q, threshold, p.exceed, shape, scale, lower.tail = TRUE, log.p = FALSE)
qGPDtail(p, threshold, p.exceed, shape, scale, lower.tail = TRUE, log.p = FALSE)
rGPDtail(n, threshold, p.exceed, shape, scale)
```

Arguments

x, q	vector of quantiles.
p	vector of probabilities.
n	number of observations.
threshold	threshold u in the POT method.
p.exceed	probability of exceeding the threshold u ; for the Smith estimator, this is $\text{mean}(x > \text{threshold})$ for x being the data.
shape	GPD shape parameter ξ (a real number).
scale	GPD scale parameter β (a positive number).
lower.tail	logical ; if TRUE (default) probabilities are $P(X \leq x)$ otherwise, $P(X > x)$.
log, log.p	logical ; if TRUE, probabilities p are given as $\log(p)$.

Details

Let u denote the threshold (threshold), p_u the exceedance probability (p.exceed) and F_{GPD} the GPD distribution function. Then the distribution function of the GPD-based tail distribution is given by

$$F(q) = 1 - p_u(1 - F_{GPD}(q - u))$$

. The quantile function is

$$F^{-1}(p) = u + F_{GPD}^{-1}(1 - (1 - p)/p_u)$$

and the density is

$$f(x) = p_u f_{GPD}(x - u)$$

, where f_{GPD} denotes the GPD density.

Note that the distribution function has a jump of height $P(X \leq u)$ ($1 - p.exceed$) at u .

Value

dGPDtail() computes the density, pGPDtail() the distribution function, qGPDtail() the quantile function and rGPDtail() random variates of the GPD-based tail distribution in the POT method.

X.. <- X.[X. > u]
plot(pF(X..), ylab = "Probability-transformed tail losses") # should be U[1-p.exceed, 1]
```

GPD_shape_plot

Fitted GPD Shape as a Function of the Threshold

Description

Fit GPDs to various thresholds and plot the fitted GPD shape as a function of the threshold.

Usage

```
GPD_shape_plot(x, thresholds = seq(quantile(x, 0.5), quantile(x, 0.99),
                                   length.out = 65),
               estimate.cov = TRUE, conf.level = 0.95,
               CI.col = adjustcolor(1, alpha.f = 0.2),
               lines.args = list(), xlim = NULL, ylim = NULL,
               xlab = "Threshold", ylab = NULL,
               xlab2 = "Excesses", plot = TRUE, ...)
```

Arguments

x	vector of numeric data.
thresholds	numeric vector of thresholds for which to fit a GPD to the excesses.
estimate.cov	logical indicating whether confidence intervals are to be computed.
conf.level	confidence level of the confidence intervals if estimate.cov.
CI.col	color of the pointwise asymptotic confidence intervals (CIs); if NA, no CIs are shown.
lines.args	list of arguments passed to the underlying lines() for drawing the shape parameter as a function of the threshold.
xlim, ylim, xlab, ylab	see plot().
xlab2	label of the secondary x-axis.
plot	logical indicating whether a plot is produced.
...	additional arguments passed to the underlying plot().

Details

Such plots can be used in the peaks-over-threshold method for determining the optimal threshold (as the smallest after which the plot is (roughly) stable).

Value

Invisibly returns a list containing the thresholds considered, the corresponding excesses and the fitted GPD objects as returned by the underlying fit_GPD_MLE().

Marius Hofert

Examples

```
set.seed(271)
X <- rt(1000, df = 3.5)
GPD_shape_plot(X)
```

hierarchical_matrix *Construction of Hierarchical Matrices*

Description

Constructing hierarchical matrices, used, for example, for hierarchical dependence models, clustering, etc.

Usage

```
hierarchical_matrix(x, diagonal = rep(1, d))
```

Arguments

x	list of length 2 or 3 containing the homogeneous numeric entry of the current block of the hierarchical matrix, the integer components belonging to the current block (or NULL) and, possibly, another (nested) list of the same type.
diagonal	diagonal elements of the hierarchical matrix.

Details

See the examples for how to use.

Value

A hierarchical **matrix** of the structure as specified in x with off-diagonal entries as specified in x and diagonal entries as specified in diagonal.

Author(s)

Marius Hofert

Examples

```

rho <- c(0.2, 0.3, 0.5, 0.8) # some entries (e.g., correlations)

## Test homogeneous case
x <- list(rho[1], 1:6)
hierarchical_matrix(x)

## Two-level case with one block of size 2
x <- list(rho[1], 1, list(rho[2], 2:3))
hierarchical_matrix(x)

## Two-level case with one block of size 2 and a larger homogeneous block
x <- list(rho[1], 1:3, list(rho[2], 4:5))
hierarchical_matrix(x)

## Test two-level case with three blocks of size 2
x <- list(rho[1], NULL, list(list(rho[2], 1:2),
                             list(rho[3], 3:4),
                             list(rho[4], 5:6)))
hierarchical_matrix(x)

## Test three-level case
x <- list(rho[1], 1:3, list(rho[2], NULL, list(list(rho[3], 4:5),
                                                list(rho[4], 6:8))))
hierarchical_matrix(x)

## Test another three-level case
x <- list(rho[1], c(3, 6, 1), list(rho[2], c(9, 2, 7, 5),
                                  list(rho[3], c(8, 4))))
hierarchical_matrix(x)

```

Hill

Hill Estimator and Plot

Description

Compute the Hill estimator and Hill plot.

Usage

```

Hill_estimator(x, k = c(10, length(x)), conf.level = 0.95)
Hill_plot(x, k = c(10, length(x)), conf.level = 0.95, Hill.estimator = NULL,
          log = "x", xlim = NULL, ylim = NULL,
          xlab = "Order statistics", ylab = "Tail index",
          CI.col = adjustcolor(1, alpha.f = 0.2), lines.args = list(),
          xaxis2 = TRUE, xlab2 = "Empirical probability", ...)

```

Arguments

<code>x</code>	vector of numeric data.
<code>k</code>	vector of length 2, determining the smallest and largest number of order statistics of <code>x</code> to compute the Hill estimator for (the smallest needs to be ≥ 2). If <code>k</code> is of length 1, <code>k</code> is expanded by <code>length(x)</code> .
<code>conf.level</code>	confidence level of the confidence intervals.
<code>Hill.estimator</code>	object as returned by <code>Hill_estimator()</code> .
<code>log, xlim, ylim, xlab, ylab</code>	see <code>plot()</code> .
<code>CI.col</code>	color of the pointwise asymptotic confidence intervals (CIs); if NA, no CIs are shown.
<code>lines.args</code>	list of additional arguments for the underlying <code>lines()</code> call to draw the Hill estimator.
<code>xaxis2</code>	logical indicating whether a third axis is drawn that shows the empirical probabilities $1-(k-1)/\text{length}(x)$ corresponding to <code>k</code> , so the value of the column <code>k.prob</code> as returned by <code>Hill_estimator()</code> .
<code>xlab2</code>	label of the secondary x-axis.
<code>...</code>	additional arguments passed to the underlying <code>plot()</code> .

Details

See McNeil et al. (2015, Section 5.2.4, (5.23))

Value

`Hill_estimator()`: A five-column matrix containing the indices `k`, their corresponding empirical probabilities `k.prob`, the estimated tail indices `tail.index`, and the lower and upper CI endpoints `CI.low` and `CI.up`.

`Hill_plot()`: Hill plot by side-effect.

Examples

```
set.seed(271)
X <- rt(1000, df = 3.5)
Y <- X[X > 0]
Hill_plot(Y)
Hill_plot(Y, log = "", CI.col = NA)
```

matrix_density_plota *Density Plot of the Values from a Lower Triangular Matrix*

Description

Density plot of all values in the lower triangular part of a matrix.

Usage

```
matrix_density_plot(x, xlab = "Entries in the lower triangular matrix",  
                   main = "", text = NULL, side = 4, line = 1, adj = 0, ...)
```

Arguments

x	matrix-like object.
xlab	x-axis label.
main	title.
text	see <code>mtext()</code> . The <code>text = ""</code> , it is omitted.
side	see <code>mtext()</code> .
line	see <code>mtext()</code> .
adj	see <code>mtext()</code> .
...	additional arguments passed to the underlying <code>plot()</code> .

Details

`matrix_density_plot()` is typically used for symmetric matrices (like correlation matrices, matrices of pairwise Kendall's tau or tail dependence parameters) to check the distribution of their off-diagonal entries.

Value

`invisible()`.

Author(s)

Marius Hofert

Examples

```
## Generate a random correlation matrix  
d <- 50  
L <- diag(1:d)  
set.seed(271)  
L[lower.tri(L)] <- runif(choose(d,2))  
Sigma <- L  
P <- cor(Sigma)  
## Density of its lower triangular entries  
matrix_density_plot(P)
```

matrix_plot

*Graphical Tool for Visualizing Matrices***Description**

Plot of a matrix.

Usage

```
matrix_plot(x, ran = range(x, na.rm = TRUE), ylim = rev(c(0.5, nrow(x) + 0.5)),
            xlab = "Column", ylab = "Row",
            scales = list(alternating = c(1,1), tck = c(1,0),
                          x = list(at = pretty(1:ncol(x)), rot = 90),
                          y = list(at = pretty(1:nrow(x)))),
            at = NULL, colorkey = NULL, col = c("royalblue3", "white", "maroon3"),
            col.regions = NULL, ...)
```

Arguments

x	matrix-like object.
ran	range (can be used to enforce (-1,1), for example).
ylim	y-axis limits in reverse order (for the rows to appear 'top down').
xlab	x-axis label.
ylab	y-axis label.
scales	see <code>levelplot()</code> ; if <code>NULL</code> , labels and ticks are omitted.
at	see <code>levelplot()</code> . If <code>NULL</code> , a useful default is computed based on the given values in x.
colorkey	see <code>levelplot()</code> . If <code>NULL</code> , a useful default is computed based on at.
col	vector of length two (if all values of x are non-positive or all are non-negative; note that also a vector of length three is allowed in this case) or three (if x contains negative and positive values) providing the color key's default colors.
col.regions	see <code>levelplot()</code> . If <code>NULL</code> , a useful default is computed based on at.
...	additional arguments passed to the underlying <code>levelplot()</code> .

Details

Plot of a matrix.

Value

The plot, a Trellis object.

Author(s)

Marius Hofert

Examples

```

## Generate a random correlation matrix
d <- 50
L <- diag(1:d)
set.seed(271)
L[lower.tri(L)] <- runif(choose(d,2)) # random Cholesky factor
Sigma <- L
P <- cor(Sigma)

## Default
matrix_plot(P)
matrix_plot(P, ran = c(-1, 1)) # within (-1, 1)
matrix_plot(abs(P)) # if nonnegative
L. <- L
diag(L.) <- NA
matrix_plot(L.) # Cholesky factor without diagonal

## Default if nonpositive
matrix_plot(-abs(P))

## Changing colors
matrix_plot(P, ran = c(-1, 1),
            col.regions = grey(c(seq(0, 1, length.out = 100),
                                seq(1, 0, length.out = 100))))

## An example with overlaid lines
library(lattice)
my_panel <- function(...) {
  panel.levelplot(...)
  panel.abline(h = c(10, 20), v = c(10, 20), lty = 2)
}
matrix_plot(P, panel = my_panel)

```

mean_excess

Mean Excess

Description

Sample mean excess function, mean excess function of a GPD and sample mean excess plot.

Usage

```

mean_excess_np(x, omit = 3)
mean_excess_plot(x, omit = 3,
                 xlab = "Threshold", ylab = "Mean excess over threshold", ...)
mean_excess_GPD(x, shape, scale)

```

Arguments

x	mean_excess_GPD(): numeric vector of evaluation points of the mean excess function of the GPD. otherwise: numeric vector of data.
omit	number ≥ 1 of unique last observations to be omitted from the sorted data (as mean excess plot becomes unreliable for these observations as thresholds).
xlab	x-axis label.
ylab	y-axis label.
...	additional arguments passed to the underlying <code>plot()</code> .
shape	GPD shape parameter ξ .
scale	GPD scale parameter β .

Details

Mean excess plots can be used in the peaks-over-threshold method for choosing a threshold. To this end, one chooses the smallest threshold above which the mean excess plot is roughly linear.

Value

`mean_excess_np()` returns a two-column matrix giving the sorted data without the omit-largest unique values (first column) and the corresponding values of the sample mean excess function (second column). It is mainly used in `mean_excess_plot()`.

`mean_excess_plot()` returns `invisible()`.

`mean_excess_GPD()` returns the mean excess function of a generalized Pareto distribution evaluated at x.

Author(s)

Marius Hofert

Examples

```
## Generate losses to work with
set.seed(271)
X <- rt(1000, df = 3.5) # in MDA(H_{1/df}); see MFE (2015, Section 16.1.1)

## (Sample) mean excess plot and threshold choice
mean_excess_plot(X[X > 0]) # we only use positive values here to see 'more'
## => Any value in [0.8, 2] seems reasonable as threshold at first sight
##   but 0.8 to 1 turns out to be too small for the degrees of
##   freedom implied by the GPD estimator to be close to the true value 3.5.
## => We go with threshold 1.5 here.
u <- 1.5 # thresholds

## An alternative way
ME <- mean_excess_np(X[X > 0])
plot(ME, xlab = "Threshold", ylab = "Mean excess over threshold")
```

```
## Mean excess plot with mean excess function of the fitted GPD
fit <- fit_GPD_MLE(X[X > u] - u)
q <- seq(u, ME[nrow(ME),"x"], length.out = 129)
MEF.GPD <- mean_excess_GPD(q-u, shape = fit$par[["shape"]], scale = fit$par[["scale"]])
mean_excess_plot(X[X > 0]) # mean excess plot for positive losses...
lines(q, MEF.GPD, col = "royalblue", lwd = 1.4) # ... with mean excess function of the fitted GPD
```

NA_plot

Graphical Tool for Visualizing NAs in a Data Set

Description

Plot NAs in a data set.

Usage

```
NA_plot(x, col = c("black", "white"), xlab = "Time", ylab = "Component",
        text = "Black: NA; White: Available data",
        side = 4, line = 1, adj = 0, ...)
```

Arguments

x	matrix (ideally an xts object).
col	bivariate vector containing the colors for missing and available data, respectively.
xlab	x-axis label.
ylab	y-axis label.
text	see <code>mtext()</code> . The text = "", it is omitted.
side	see <code>mtext()</code> .
line	see <code>mtext()</code> .
adj	see <code>mtext()</code> .
...	additional arguments passed to the underlying <code>image()</code> .

Details

Indicate [NAs](#) in a data set.

Value

`invisible()`.

Author(s)

Marius Hofert

Examples

```
## Generate data
n <- 1000 # sample size
d <- 100 # dimension
set.seed(271) # set seed
x <- matrix(runif(n*d), ncol = d) # generate data

## Assign missing data
k <- ceiling(d/4) # fraction of columns with some NAs
j <- sample(1:d, size = k) # columns j with NAs
i <- sample(1:n, size = k) # 1:i will be NA in each column j
X <- x
for(k. in seq_len(k)) X[1:i[k.], j[k.]] <- NA # put in NAs

## Plot NAs
NA_plot(X) # indicate NAs
```

pp_qq_plot

*P-P and Q-Q Plots***Description**

Probability-probability plots and quantile-quantile plots.

Usage

```
pp_plot(x, FUN, pch = 20, xlab = "Theoretical probabilities",
        ylab = "Sample probabilities", ...)
qq_plot(x, FUN = qnorm, method = c("theoretical", "empirical"),
        pch = 20, do.qqline = TRUE, qqline.args = NULL,
        xlab = "Theoretical quantiles", ylab = "Sample quantiles",
        ...)
```

Arguments

x	data vector .
FUN	function . For pp_plot(): The distribution function (vectorized). qq_plot(): The quantile function (vectorized).
pch	plot symbol.
xlab	x-axis label.
ylab	y-axis label.
do.qqline	logical indicating whether a Q-Q line is plotted.

method	method used to construct the Q-Q line. If "theoretical", the theoretically true line with intercept 0 and slope 1 is displayed; if "empirical", the intercept and slope are determined with <code>qqline()</code> . The former helps deciding whether <code>x</code> comes from the distribution specified by <code>FUN</code> exactly, the latter whether <code>x</code> comes from a location-scale transformed distribution specified by <code>FUN</code> .
qqline.args	<code>list</code> containing additional arguments passed to the underlying <code>abline()</code> functions. Defaults to <code>list(a = 0, b = 1)</code> if <code>method = "theoretical"</code> and <code>list()</code> if <code>method = "empirical"</code> .
...	additional arguments passed to the underlying <code>plot()</code> .

Details

Note that Q-Q plots are more widely used than P-P plots (as they highlight deviations in the tails more clearly).

Value

`invisible()`.

Author(s)

Marius Hofert

Examples

```
## Generate data
n <- 1000
mu <- 1
sig <- 3
nu <- 3.5
set.seed(271) # set seed
x <- mu + sig * sqrt((nu-2)/nu) * rt(n, df = nu) # sample from t_nu(mu, sig^2)

## P-P plot
pF <- function(q) pt((q - mu) / (sig * sqrt((nu-2)/nu)), df = nu)
pp_plot(x, FUN = pF)

## Q-Q plot
qF <- function(p) mu + sig * sqrt((nu-2)/nu) * qt(p, df = nu)
qq_plot(x, FUN = qF)

## A comparison with R's qqplot() and qqline()
qqplot(qF(ppoints(length(x))), x) # the same (except labels)
qqline(x, distribution = qF) # slightly different (since *estimated*)

## Difference of the two methods
set.seed(271)
z <- rnorm(1000)
## Standardized data
qq_plot(z, FUN = qnorm) # fine
qq_plot(z, FUN = qnorm, method = "empirical") # fine
```

```
## Location-scale transformed data
mu <- 3
sig <- 2
z. <- mu+sig*z
qq_plot(z., FUN = qnorm) # not fine (z. comes from N(mu, sig^2), not N(0,1))
qq_plot(z., FUN = qnorm, method = "empirical") # fine (as intercept and slope are estimated)
```

returns

*Computing Returns and Inverse Transformation***Description**

Compute log-returns, simple returns and basic differences (or the inverse operations) from given data.

Usage

```
returns(x, method = c("logarithmic", "simple", "diff"), inverse = FALSE,
        start, start.date)
returns_qrmtools(x, method = c("logarithmic", "simple", "diff"),
                 inverse = FALSE, start, start.date)
```

Arguments

x	matrix or vector (possibly a xts object) to be turned into returns (if inverse = FALSE) or returns to be turned into the original data (if inverse = TRUE).
method	character string indicating the method to be used (log-returns (logarithmic changes), simple returns (relative changes), or basic differences). Note that this can also be a vector of such methods of length equal to the number of columns of x.
inverse	logical indicating whether the inverse transformation (data from given returns) shall be computed (if TRUE, this requires start to be specified).
start	if inverse = TRUE, the last available value of the time series to be constructed from the given returns x.
start.date	character or Date object to be used as the date corresponding to the value start; currently only used for xts objects.

Details

If inverse = FALSE and x is an xts object, the returned object is an xts, too.

Note that the R package **timeSeries** also contains a function returns() (and hence the order in which **timeSeries** and **qrmtools** are loaded matters to get the right returns()). For this reason, returns_qrmtools() is an alias for returns() from **qrmtools**.

Value

[vector](#) or [matrix](#) with the same number of columns as x just one row less if inverse = FALSE or one row more if inverse = TRUE.

Author(s)

Marius Hofert

Examples

```

## Generate two paths of a geometric Brownian motion
S0 <- 10 # current stock price S_0
r <- 0.01 # risk-free annual interest rate
sig <- 0.2 # (constant) annual volatility
T <- 2 # maturity in years
N <- 250 # business days per year
t <- 1:(N*T) # time points to be sampled
npath <- 2 # number of paths
set.seed(271) # for reproducibility
S <- replicate(npath, S0 * exp(cumsum(rnorm(N*T, # sample paths of S_t
                                     mean = (r-sig^2/2)/N,
                                     sd = sqrt((sig^2)/N)))) # (N*T, npath)

## Turn into xts objects
library(xts)
sdate <- as.Date("2000-05-02") # start date
S. <- as.xts(S, order.by = seq(sdate, length.out = N*T, by = "1 week"))
plot(S.[,1], main = "Stock 1")
plot(S.[,2], main = "Stock 2")

### Log-returns #####

## Based on S[,1]
X <- returns(S[,1]) # build log-returns (one element less than S)
Y <- returns(X, inverse = TRUE, start = S[1,1]) # transform back
stopifnot(all.equal(Y, S[,1]))

## Based on S
X <- returns(S) # build log-returns (one element less than S)
Y <- returns(X, inverse = TRUE, start = S[1,]) # transform back
stopifnot(all.equal(Y, S))

## Based on S.[,1]
X <- returns(S.[,1])
Y <- returns(X, inverse = TRUE, start = S.[1,1], start.date = sdate)
stopifnot(all.equal(Y, S.[,1], check.attributes = FALSE))

## Based on S.
X <- returns(S.)
Y <- returns(X, inverse = TRUE, start = S.[1], start.date = sdate)
stopifnot(all.equal(Y, S., check.attributes = FALSE))

## Sign-adjusted (negative) log-returns
X <- -returns(S) # build -log-returns
Y <- returns(-X, inverse = TRUE, start = S[1,]) # transform back
stopifnot(all.equal(Y, S))

```

```

### Simple returns #####

## Simple returns based on S
X <- returns(S, method = "simple")
Y <- returns(X, method = "simple", inverse = TRUE, start = S[,1])
stopifnot(all.equal(Y, S))

## Simple returns based on S.
X <- returns(S., method = "simple")
Y <- returns(X, method = "simple", inverse = TRUE, start = S[,1],
             start.date = sdate)
stopifnot(all.equal(Y, S., check.attributes = FALSE))

## Sign-adjusted (negative) simple returns
X <- -returns(S, method = "simple")
Y <- returns(-X, method = "simple", inverse = TRUE, start = S[,1])
stopifnot(all.equal(Y, S))

### Basic differences #####

## Basic differences based on S
X <- returns(S, method = "diff")
Y <- returns(X, method = "diff", inverse = TRUE, start = S[,1])
stopifnot(all.equal(Y, S))

## Basic differences based on S.
X <- returns(S., method = "diff")
Y <- returns(X, method = "diff", inverse = TRUE, start = S[,1],
             start.date = sdate)
stopifnot(all.equal(Y, S., check.attributes = FALSE))

## Sign-adjusted (negative) basic differences
X <- -returns(S, method = "diff")
Y <- returns(-X, method = "diff", inverse = TRUE, start = S[,1])
stopifnot(all.equal(Y, S))

### Vector-case of 'method' #####

X <- returns(S., method = c("logarithmic", "diff"))
Y <- returns(X, method = c("logarithmic", "diff"), inverse = TRUE, start = S[,1],
             start.date = sdate)
stopifnot(all.equal(Y, S., check.attributes = FALSE))

```

Description

Computing risk measures.

Usage

```
## Value-at-risk
VaR_np(x, level, names = FALSE, type = 1, ...)
VaR_t(level, loc = 0, scale = 1, df = Inf)
VaR_t01(level, df = Inf)
VaR_GPD(level, shape, scale)
VaR_Par(level, shape, scale = 1)
VaR_GPDtail(level, threshold, p.exceed, shape, scale)

## Expected shortfall
ES_np(x, level, method = c(">", ">="), verbose = FALSE, ...)
ES_t(level, loc = 0, scale = 1, df = Inf)
ES_t01(level, df = Inf)
ES_GPD(level, shape, scale)
ES_Par(level, shape, scale = 1)
ES_GPDtail(level, threshold, p.exceed, shape, scale)

## Range value-at-risk
RVaR_np(x, level, ...)

## Multivariate geometric value-at-risk and expectiles
gVaR(x, level, start = colMeans(x),
     method = if(length(level) == 1) "Brent" else "Nelder-Mead", ...)
gEX(x, level, start = colMeans(x),
    method = if(length(level) == 1) "Brent" else "Nelder-Mead", ...)
```

Arguments

x	gVaR(), gEX(): matrix of (rowwise) multivariate losses. VaR_np(), ES_np(), RVaR_np(): if x is a matrix then <code>rowSums()</code> is applied first (so value-at-risk and expected shortfall of the sum is computed). otherwise: vector of losses.
level	RVaR_np(): vector of length 1 or 2 giving the lower and upper confidence level; if of length 1, it is interpreted as the lower confidence level and the upper one is taken to be 1. gVaR(), gEX(): vector or matrix of (rowwise) confidence levels α (all in $[0, 1]$). otherwise: confidence level $\alpha \in [0, 1]$.
names	see <code>?quantile</code> .
type	see <code>?quantile</code> .
loc	location parameter μ .
shape	VaR_GPD(), ES_GPD(): GPD shape parameter ξ , a real number.

	VaR_Par(), ES_Par(): Pareto shape parameter θ , a positive number.
scale	VaR_t(), ES_t(): t scale parameter σ , a positive number. VaR_GPD(), ES_GPD(): GPD scale parameter β , a positive number. VaR_Par(), ES_Par(): Pareto scale parameter κ , a positive number.
df	degrees of freedom, a positive number; choose df = Inf for the normal distribution. For the standardized t distributions, df has to be greater than 2.
threshold	threshold u (used to estimate the exceedance probability based on the data x).
p.exceed	exceedance probability; typically $\text{mean}(x > \text{threshold})$ for x being the data modeled with the peaks-over-threshold (POT) method.
start	vector of initial values for the underlying <code>optim()</code> .
method	ES_np(): character string indicating the method for computing expected shortfall. gVaR(), gEX(): the optimization method passed to the underlying <code>optim()</code> .
verbose	logical indicating whether verbose output is given (in case the mean is computed over (too) few observations).
...	VaR_np(): additional arguments passed to the underlying <code>quantile()</code> . ES_np(), RVaR_np(): additional arguments passed to the underlying <code>VaR_np()</code> . gVaR(), gEX(): additional arguments passed to the underlying <code>optim()</code> .

Details

The distribution function of the Pareto distribution is given by

$$F(x) = 1 - (\kappa/(\kappa + x))^\theta, \quad x \geq 0,$$

where $\theta > 0$, $\kappa > 0$.

Value

VaR_np(), ES_np(), RVaR_np() estimate value-at-risk, expected shortfall and range value-at-risk non-parametrically. For expected shortfall, if method = ">=" (method = ">", the default), losses greater than or equal to (strictly greater than) the nonparametric value-at-risk estimate are averaged; in the former case, there might be no such loss, in which case NaN is returned. For range value-at-risk, losses greater than the nonparametric VaR estimate at level level[1] and less than or equal to the nonparametric VaR estimate at level level[2] are averaged.

VaR_t(), ES_t() compute value-at-risk and expected shortfall for the t (or normal) distribution. VaR_t01(), ES_t01() compute value-at-risk and expected shortfall for the standardized t (or normal) distribution, so scaled t distributions to have mean 0 and variance 1; note that they require a degrees of freedom parameter greater than 2.

VaR_GPD(), ES_GPD() compute value-at-risk and expected shortfall for the generalized Pareto distribution (GPD).

VaR_Par(), ES_Par() compute value-at-risk and expected shortfall for the Pareto distribution.

gVaR(), gEX() compute the multivariate geometric value-at-risk and expectiles suggested by Chaudhuri (1996) and Herrmann et al. (2018), respectively.

mtext(lab, side = 4, line = 1, adj = 0)

```

Description

Plotting step functions, empirical distribution functions and empirical quantile functions.

Usage

```
step_plot(x, y, y0 = NA, x0 = NA, x1 = NA, method = c("edf", "eqf"), log = "",
          verticals = NA, do.points = NA, add = FALSE,
          col = par("col"), main = "", xlab = "x", ylab = "Function value at x",
          plot.args = NULL, segments.args = NULL, points.args = NULL)
edf_plot(x, y0 = 0, x0 = NA, x1 = NA, log = "",
          verticals = NA, do.points = NA, col = par("col"),
          main = "", xlab = "x", ylab = "Distribution function at x", ...)
eqf_plot(x, y0 = NA, x0 = 0, x1 = 1, log = "",
          verticals = NA, do.points = NA, col = par("col"),
          main = "", xlab = "x", ylab = "Quantile function at x", ...)
```

Arguments

x	step_plot(): numeric vector of x-values. edf_plot(): numeric vector or a list of numeric vectors; if a list, each element corresponds to the x-values of an empirical distribution function. eqf_plot(): similar to edf_plot().
y	y-values corresponding to x.
y0	y-value of the graph extending to the left of the first x-value.
x0	smallest x-value.
x1	largest x-value.
method	character string indicating the type of method to be used ("edf" for empirical distribution function types of plots and "eqf" for empirical quantile function types).
log	character indicating whether a logarithmic x-axis is used.
verticals	logical indicating whether to plot vertical lines (defaults to TRUE if and only if there are 100 or more data points).
do.points	logical (vector) indicating whether points are to be plotted (defaults to TRUE if and only if there are less than 100 data points).
add	logical indicating whether the current plot is added to the last one.
col	color (for edf_plot() this can be a vector).
main	title.
xlab	x-axis label.
ylab	y-axis label.
plot.args	list of additional arguments passed to the underlying plot().
segments.args	list of additional arguments passed to the underlying segments().
points.args	list of additional arguments passed to the underlying points().
...	additional arguments passed to the underlying step_plot().

Value

Nothing (plot by side-effect).

Author(s)

Marius Hofert

Examples

```
x <- c(5, 2, 4, 2, 3, 2, 2, 2, 1, 2) # example data
edf_plot(x) # empirical distribution function (edf)
edf_plot(x, log = "x")
edf_plot(x, verticals = TRUE)
edf_plot(x, do.points = FALSE)
cols <- c("black", "royalblue3")
edf_plot(list(x, x+2), col = cols) # edf with shifted edf
edf_plot(list(x, x+2), col = cols, x0 = 0.5, x1 = 7.5)
edf_plot(list(x, x+2), col = cols, x0 = 0.5, x1 = 7.5, verticals = TRUE)
eqf_plot(x) # empirical quantile function
eqf_plot(x, verticals = TRUE)
```

tail_plot

Plot of an Empirical Survival Function with Smith Estimator

Description

Plot an empirical tail survival function, possibly overlaid with the Smith estimator.

Usage

```
tail_plot(x, threshold, shape = NULL, scale = NULL,
          q = NULL, length.out = 129, lines.args = list(),
          log = "xy", xlim = NULL, ylim = NULL,
          xlab = "x", ylab = "Tail probability at x", ...)
```

Arguments

x	numeric vector of data.
threshold	numeric(1) giving the threshold u above which the tail (starts and) is to be plotted.
shape	NULL or the GPD shape parameter ξ (typically obtained via <code>fit_GPD_MLE()</code>).
scale	NULL or the GPD shape parameter β (typically obtained via <code>fit_GPD_MLE()</code>).
q	NULL, numeric(1) or numeric vector of evaluation points of the Smith estimator (semi-parametric GPD-based tail estimator in the POT method). If NULL, the evaluation points are determined internally as an equidistant sequence of length <code>length.out</code> between the smallest and largest exceedance (taken equidistant in log-scale if <code>log</code> contains "x"). If numeric(1), then the behavior is similar to

	NULL with the exception that the plot is extended to the right of the largest exceedance if q is larger than the largest exceedance.
length.out	length of q .
lines.args	list of arguments passed to the underlying lines() .
log	character indicating whether logarithmic axes are to be used.
xlim	x-axis limits.
ylim	y-axis limits.
xlab	x-axis label.
ylab	y-axis label.
...	additional arguments passed to the underlying plot() .

Value

If both `shape` and `scale` are provided, `tail_plot()` overlays the empirical tail survival function estimator (evaluated at the exceedances) with the corresponding GPD. In this case, `tail_plot()` invisibly returns a list with two two-column matrices, one containing the x-values and y-values of the empirical survival distribution estimator and one containing the x-values and y-values of the Smith estimator. If `shape` or `scale` are NULL, `tail_plot()` invisibly returns a two-column matrix with the x-values and y-values of the empirical survival distribution estimator.

Examples

```
## Generate losses to work with
set.seed(271)
X <- rt(1000, df = 3.5) # in MDA(H_{1/df}); see MFE (2015, Section 16.1.1)

## Threshold (see ?dGPDtail, for example)
u <- 1.5 # threshold

## Plots of empirical survival distribution functions (overlaid with Smith estimator)
tail_plot(X, threshold = u, log = "", type = "b") # => need log-scale
tail_plot(X, threshold = u, type = "s") # as a step function
fit <- fit_GPD_MLE(X[X > u] - u) # fit GPD to excesses (POT method)
tail_plot(X, threshold = u, # without log-scale
          shape = fit$par[["shape"]], scale = fit$par[["scale"]], log = "")
tail_plot(X, threshold = u, # highlights linearity
          shape = fit$par[["shape"]], scale = fit$par[["scale"]])
```

Description

Compute formal tests based on the Mahalanobis distances and Mahalanobis angles of multivariate normality (including Mardia's kurtosis test and Mardia's skewness test).

Usage

```
maha2_test(x, type = c("ad.test", "ks.test"), dist = c("chi2", "beta"), ...)
mardia_test(x, type = c("kurtosis", "skewness"), method = c("direct", "chol"))
```

Arguments

x	(n, d)-matrix of data.
type	character string indicating the type of test: "ad.test": Anderson-Darling test as computed by the underlying <code>ad.test()</code> . "ks.test": Kolmogorov-Smirnov test as computed by the underlying <code>ks.test()</code> . "kurtosis": Mardia's kurtosis test (based on Mahalanobis distances). "skewness": Mardia's skewness test (based on Mahalanobis angles).
dist	distribution to check against.
method	method for computing the Mahalanobis angles.
...	additional arguments passed to the underlying <code>ad.test()</code> or <code>ks.test()</code> .

Value

An `htest` object (for `maha2_test` the one returned by the underlying `ad.test()` or `ks.test()`).

Author(s)

Marius Hofert

Examples

```
set.seed(271)
U <- matrix(runif(3 * 200), ncol = 3)
X <- cbind(qexp(U[,1]), qnorm(U[,2:3]))
maha2_test(X) # at the 'edge' of rejecting
maha2_test(X, type = "ks.test") # at the 'edge', too
mardia_test(X) # clearly rejects at 5%
mardia_test(X, type = "skewness") # clearly rejects at 5%
```

 VaR_ES_bounds_analytical

“Analytical” Best and Worst Value-at-Risk for Given Marginals

Description

Compute the best and worst Value-at-Risk (VaR) for given marginal distributions with an “analytical” method.

Usage

```
## ``Analytical`` methods
crude_VaR_bounds(level, qF, d = NULL, ...)
VaR_bounds_hom(level, d, method = c("Wang", "Wang.Par", "dual"),
               interval = NULL, tol = NULL, ...)
dual_bound(s, d, pF, tol = .Machine$double.eps^0.25, ...)
```

Arguments

level	confidence level α for VaR and ES (e.g., 0.99).
qF	d-list containing the marginal quantile functions. In the homogeneous case, qF can also be a single function.
d	dimension (number of risk factors; ≥ 2). For <code>crude_VaR_bounds()</code> , d only needs to be given in the homogeneous case in which qF is a function .
method	character string. <code>method = "Wang"</code> and <code>method = "Wang.Par"</code> apply the approach of McNeil et al. (2015, Proposition 8.32) for computing best (i.e., smallest) and worst (i.e., largest) VaR. The latter method assumes Pareto margins and thus does not require numerical integration. <code>method = "dual"</code> applies the dual bound approach as in Embrechts et al. (2013, Proposition 4) for computing worst VaR (no value for the best VaR can be obtained with this approach and thus NA is returned for the best VaR).
interval	initial interval (a numeric(2)) for computing worst VaR. If not provided, these are the defaults chosen: <code>method = "Wang"</code> : initial interval is $[0, (1 - \alpha)/d]$. <code>method = "Wang.Par"</code> : initial interval is $[c_l, c_u]$, where c_l and c_u are chosen as in Hofert et al. (2015). <code>method = "dual"</code> : in this case, no good defaults are known. Note that the lower endpoint of the initial interval has to be sufficiently large in order for the the inner root-finding algorithm to find a root; see Details .
tol	tolerance for uniroot() for computing worst VaR. This defaults (for <code>tol = NULL</code>) to 2.2204×10^{-16} for <code>method = "Wang"</code> or <code>method = "Wang.Par"</code> (where a smaller tolerance is crucial) and to uniroot() 's default <code>.Machine\$double.eps^0.25</code> otherwise. Note that for <code>method = "dual"</code> , <code>tol</code> is used for both the outer and the inner root-finding procedure.

s	dual bound evaluation point.
pF	marginal loss distribution function (homogeneous case only).
...	crude_VaR_bounds(): ellipsis argument passed to (all provided) quantile functions.
	VaR_bounds_hom(): case method = "Wang" requires the quantile function qF() to be provided and additional arguments passed via the ellipsis argument are passed on to the underlying <code>integrate()</code> . For method = "Wang.Par" the ellipsis argument must contain the parameter shape (the shape parameter $\theta > 0$ of the Pareto distribution). For method = "dual", the ellipsis argument must contain the distribution function pF() and the initial interval interval for the outer root finding procedure (not for $d = 2$); additional arguments are passed on to the underlying <code>integrate()</code> for computing the dual bound $D(s)$.
	dual_bound(): ellipsis argument is passed to the underlying <code>integrate()</code> .

Details

For $d = 2$, `VaR_bounds_hom()` uses the method of Embrechts et al. (2013, Proposition 2). For `method = "Wang"` and `method = "Wang.Par"` the method presented in McNeil et al. (2015, Prop. 8.32) is implemented; this goes back to Embrechts et al. (2014, Prop. 3.1; note that the published version of this paper contains typos for both bounds). This requires one `uniroot()` and, for the generic `method = "Wang"`, one `integrate()`. The critical part for the generic `method = "Wang"` is the lower endpoint of the initial interval for `uniroot()`. If the (marginal) distribution function has finite first moment, this can be taken as 0. However, if it has infinite first moment, the lower endpoint has to be positive (but must lie below the unknown root). Note that the upper endpoint $(1 - \alpha)/d$ also happens to be a root and thus one needs a proper initial interval containing the root and being strictly contained in $(0, (1 - \alpha)/d)$. In the case of Pareto margins, Hofert et al. (2015) have derived such an initial (which is used by `method = "Wang.Par"`). Also note that the chosen smaller default tolerances for `uniroot()` in case of `method = "Wang"` and `method = "Wang.Par"` are crucial for obtaining reliable VaR values; see Hofert et al. (2015).

For `method = "dual"` for computing worst VaR, the method presented of Embrechts et al. (2013, Proposition 4) is implemented. This requires two (nested) `uniroot()`, and an `integrate()`. For the inner root-finding procedure to find a root, the lower endpoint of the provided initial interval has to be "sufficiently large".

Note that these approaches for computing the VaR bounds in the homogeneous case are numerically non-trivial; see the source code and `vignette("VaR_bounds", package = "qrmtools")` for more details. As a rule of thumb, use `method = "Wang"` if you have to (i.e., if the margins are not Pareto) and `method = "Wang.Par"` if you can (i.e., if the margins are Pareto). It is not recommended to use (the numerically even more challenging) `method = "dual"`.

Value

`crude_VaR_bounds()` returns crude lower and upper bounds for VaR at confidence level α for any d -dimensional model with marginal quantile functions specified by `qF`.

`VaR_bounds_hom()` returns the best and worst VaR at confidence level α for d risks with equal distribution function specified by the ellipsis ...

`dual_bound()` returns the value of the dual bound $D(s)$ as given in Embrechts, Puccetti, Rüschendorf (2013, Eq. (12)).

Worst and Best Value-at-Risk and Best Expected Shortfall for Given Marginals via Rearrangements

Description

Compute the worst and best Value-at-Risk (VaR) and the best expected shortfall (ES) for given marginal distributions via rearrangements.

Usage

```

## Workhorses
## Column rearrangements
rearrange(X, tol = 0, tol.type = c("relative", "absolute"),
          n.lookback = ncol(X), max.ra = Inf,
          method = c("worst.VaR", "best.VaR", "best.ES"),
          sample = TRUE, is.sorted = FALSE, trace = FALSE, ...)
## Block rearrangements
block_rearrange(X, tol = 0, tol.type = c("absolute", "relative"),
               n.lookback = ncol(X), max.ra = Inf,
               method = c("worst.VaR", "best.VaR", "best.ES"),
               sample = TRUE, trace = FALSE, ...)

## User interfaces
## Rearrangement Algorithm
RA(level, qF, N, abstol = 0, n.lookback = length(qF), max.ra = Inf,
   method = c("worst.VaR", "best.VaR", "best.ES"), sample = TRUE)
## Adaptive Rearrangement Algorithm
ARA(level, qF, N.exp = seq(8, 19, by = 1), reltol = c(0, 0.01),
     n.lookback = length(qF), max.ra = 10*length(qF),
     method = c("worst.VaR", "best.VaR", "best.ES"),
     sample = TRUE)
## Adaptive Block Rearrangement Algorithm
ABRA(level, qF, N.exp = seq(8, 19, by = 1), absreltol = c(0, 0.01),
      n.lookback = NULL, max.ra = Inf,
      method = c("worst.VaR", "best.VaR", "best.ES"),
      sample = TRUE)

```

Arguments

<code>X</code>	(N, d)-matrix of quantiles (to be rearranged). If <code>is.sorted</code> it is assumed that the columns of <code>X</code> are sorted in <i>increasing</i> order.
<code>tol</code>	(absolute or relative) tolerance to determine (the individual) convergence. This should normally be a number greater than or equal to 0, but <code>rearrange()</code> also allows for <code>tol = NULL</code> which means that columns are rearranged until each column is oppositely ordered to the sum of all other columns.
<code>tol.type</code>	character string indicating the type of convergence tolerance function to be used ("relative" for relative tolerance and "absolute" for absolute tolerance).
<code>n.lookback</code>	number of rearrangements to look back for deciding about numerical convergence. Use this option with care.
<code>max.ra</code>	maximal number of (considered) column rearrangements of the underlying matrix of quantiles (can be set to <code>Inf</code>).
<code>method</code>	character string indicating whether bounds for the worst/best VaR or the best ES should be computed. These bounds are termed \underline{s}_N and \bar{s}_N in the literature (and below) and are theoretically not guaranteed bounds of worst/best VaR or

	best ES; however, they are treated as such in practice and are typically in line with results from <code>VaR_bounds_hom()</code> in the homogeneous case, for example.
<code>sample</code>	<code>logical</code> indicating whether each column of the two underlying matrices of quantiles (see Step 3 of the Rearrangement Algorithm in Embrechts et al. (2013)) are randomly permuted before the rearrangements begin. This typically has quite a positive effect on run time (as most of the time is spent (oppositely) ordering columns (for <code>rearrange()</code>) or blocks (for <code>block_rearrange()</code>)).
<code>is.sorted</code>	<code>logical</code> indicating whether the columns of X are sorted in increasing order.
<code>trace</code>	<code>logical</code> indicating whether the underlying matrix is printed after each rearrangement step. See <code>vignette("VaR_bounds", package = "qrmtools")</code> for how to interpret the output.
<code>level</code>	confidence level α for VaR and ES (e.g., 0.99).
<code>qF</code>	d-list containing the marginal quantile functions.
<code>N</code>	number of discretization points.
<code>abstol</code>	absolute convergence tolerance ϵ to determine the individual convergence, i.e., the change in the computed minimal row sums (for <code>method = "worst.VaR"</code>) or maximal row sums (for <code>method = "best.VaR"</code>) or expected shortfalls (for <code>method = "best.ES"</code>) for the lower bound \underline{s}_N and the upper bound \bar{s}_N . <code>abstol</code> is typically ≥ 0 ; it can also be <code>NULL</code> , see <code>tol</code> above.
<code>N.exp</code>	exponents of the number of discretization points (a <code>vector</code>) over which the algorithm iterates to find the smallest number of discretization points for which the desired accuracy (specified by <code>abstol</code> and <code>reltol</code>) is attained; for each number of discretization points, at most <code>max.ra</code> -many column rearrangements are of the underlying matrix of quantiles are considered.
<code>reltol</code>	<code>vector</code> of length two containing the individual (first component; used to determine convergence of the minimal row sums (for <code>method = "worst.VaR"</code>) or maximal row sums (for <code>method = "best.VaR"</code>) or expected shortfalls (for <code>method = "best.ES"</code>) for \underline{s}_N and \bar{s}_N) and the joint (second component; relative tolerance between the computed \underline{s}_N and \bar{s}_N with respect to \bar{s}_N) relative convergence tolerances. <code>reltol</code> can also be of length one in which case it denotes the joint relative tolerance; the individual relative tolerance is taken as <code>NULL</code> (see <code>tol</code> above) in this case.
<code>absreltol</code>	<code>vector</code> of length two containing the individual (first component; used to determine convergence of the minimal row sums (for <code>method = "worst.VaR"</code>) or maximal row sums (for <code>method = "best.VaR"</code>) or expected shortfalls (for <code>method = "best.ES"</code>) for \underline{s}_N and \bar{s}_N) absolute and the joint (second component; relative tolerance between the computed \underline{s}_N and \bar{s}_N with respect to \bar{s}_N) relative convergence tolerances. <code>absreltol</code> can also be of length one in which case it denotes the joint relative tolerance; the individual absolute tolerance is taken as 0 in this case.
<code>...</code>	additional arguments passed to the underlying optimization function. Currently, this is only used if <code>method = "best.ES"</code> in which case the required confidence level α must be provided as argument <code>level</code> .

Details

`rearrange()` is an auxiliary function (workhorse). It is called by `RA()` and `ARA()`. After a column rearrangement of X , the tolerance between the minimal row sum (for the worst VaR) or maximal row sum (for the best VaR) or expected shortfall (obtained from the row sums; for the best ES) after this rearrangement and the one of $n.lookback$ rearrangement steps before is computed and convergence determined. For performance reasons, no input checking is done for `rearrange()` and it can change in future versions to (further) improve run time. Overall it should only be used by experts.

`block_rearrange()`, the workhorse underlying `ABRA()`, is similar to `rearrange()` in that it checks whether convergence has occurred after every rearrangement by comparing the change to the row sum variance from $n.lookback$ rearrangement steps back. `block_rearrange()` differs from `rearrange()` in the following ways. First, instead of single columns, whole (randomly chosen) blocks (two at a time) are chosen and oppositely ordered. Since some of the ideas for improving the speed of `rearrange()` do not carry over to `block_rearrange()`, the latter should in general not be as fast as the former. Second, instead of using minimal or maximal row sums or expected shortfall to determine numerical convergence, `block_rearrange()` uses the variance of the vector of row sums to determine numerical convergence. By default, it targets a variance of 0 (which is also why the default `tol.type` is "absolute").

For the Rearrangement Algorithm `RA()`, convergence of \underline{s}_N and \bar{s}_N is determined if the minimal row sum (for the worst VaR) or maximal row sum (for the best VaR) or expected shortfall (obtained from the row sums; for the best ES) satisfies the specified `abstol` (so $\leq \epsilon$) after at most `max.ra`-many column rearrangements. This is different from Embrechts et al. (2013) who use $< \epsilon$ and only check for convergence after an iteration through all columns of the underlying matrix of quantiles has been completed.

For the Adaptive Rearrangement Algorithm `ARA()` and the Adaptive Block Rearrangement Algorithm `ABRA()`, convergence of \underline{s}_N and \bar{s}_N is determined if, after at most `max.ra`-many column rearrangements, the (the individual relative tolerance) `reltol[1]` is satisfied *and* the relative (joint) tolerance between both bounds is at most `reltol[2]`.

Note that `RA()`, `ARA()` and `ABRA()` need to evaluate the 0-quantile (for the lower bound for the best VaR) and the 1-quantile (for the upper bound for the worst VaR). As the algorithms, due to performance reasons, can only handle finite values, the 0-quantile and the 1-quantile need to be adjusted if infinite. Instead of the 0-quantile, the $\alpha/(2N)$ -quantile is computed and instead of the 1-quantile the $\alpha + (1 - \alpha)(1 - 1/(2N))$ -quantile is computed for such margins (if the 0-quantile or the 1-quantile is finite, no adjustment is made).

`rearrange()`, `block_rearrange()`, `RA()`, `ARA()` and `ABRA()` compute \underline{s}_N and \bar{s}_N which are, from a practical point of view, treated as bounds for the worst (i.e., largest) or the best (i.e., smallest) VaR or the best (i.e., smallest ES), but which are not known to be such bounds from a theoretical point of view; see also above. Calling them “bounds” for worst/best VaR or best ES is thus theoretically not correct (unless proven) but “practical”. The literature thus speaks of $(\underline{s}_N, \bar{s}_N)$ as the rearrangement gap.

Value

`rearrange()` and `block_rearrange()` return a `list` containing

bound: computed \underline{s}_N or \bar{s}_N .

- tol:** reached tolerance (i.e., the (absolute or relative) change of the minimal row sum (for method = "worst.VaR") or maximal row sum (for method = "best.VaR") or expected shortfall (for method = "best.ES") after the last rearrangement).
- converged:** **logical** indicating whether the desired (absolute or relative) tolerance **tol** has been reached.
- opt.row.sums:** **vector** containing the computed optima (minima for method = "worst.VaR"; maxima for method = "best.VaR"; expected shortfalls for method = "best.ES") for the row sums after each (considered) rearrangement.
- X.rearranged:** (N, d)-**matrix** containing the rearranged X.
- X.rearranged.opt.row:** **vector** containing the row of X.rearranged which leads to the final optimal sum. If there is more than one such row, the columnwise averaged row is returned.
- RA()** returns a **list** containing
- bounds:** bivariate vector containing the computed \underline{s}_N and \bar{s}_N (the so-called rearrangement range) which are typically treated as bounds for worst/best VaR or best ES; see also above.
- rel.ra.gap:** reached relative tolerance (also known as relative rearrangement gap) between \underline{s}_N and \bar{s}_N computed with respect to \bar{s}_N .
- ind.abs.tol:** bivariate **vector** containing the reached individual absolute tolerances (i.e., the absolute change of the minimal row sums (for method = "worst.VaR") or maximal row sums (for method = "best.VaR") or expected shortfalls (for method = "best.ES") for computing \underline{s}_N and \bar{s}_N ; see also **tol** returned by **rearrange()** above).
- converged:** bivariate **logical** vector indicating convergence of the computed \underline{s}_N and \bar{s}_N (i.e., whether the desired tolerances were reached).
- num.ra:** bivariate vector containing the number of column rearrangements of the underlying matrices of quantiles for \underline{s}_N and \bar{s}_N .
- opt.row.sums:** **list** of length two containing the computed optima (minima for method = "worst.VaR"; maxima for method = "best.VaR"; expected shortfalls for method = "best.ES") for the row sums after each (considered) column rearrangement for the computed \underline{s}_N and \bar{s}_N ; see also **rearrange()**.
- X:** initially constructed (N, d)-matrices of quantiles for computing \underline{s}_N and \bar{s}_N .
- X.rearranged:** rearranged matrices X for \underline{s}_N and \bar{s}_N .
- X.rearranged.opt.row:** rows corresponding to optimal row sum (see X.rearranged.opt.row as returned by **rearrange()**) for \underline{s}_N and \bar{s}_N .
- ARA()** and **ABRA()** return a **list** containing
- bounds:** see **RA()**.
- rel.ra.gap:** see **RA()**.
- tol:** trivariate **vector** containing the reached individual (relative for **ARA()**; absolute for **ABRA()**) tolerances and the reached joint relative tolerance (computed with respect to \bar{s}_N).
- converged:** trivariate **logical vector** indicating individual convergence of the computed \underline{s}_N (first entry) and \bar{s}_N (second entry) and indicating joint convergence of the two bounds according to the attained joint relative tolerance (third entry).
- N.used:** actual N used for computing the (final) \underline{s}_N and \bar{s}_N .

num.ra: see RA(); computed for N. used.
 opt.row.sums: see RA(); computed for N. used.
 X: see RA(); computed for N. used.
 X.rearranged: see RA(); computed for N. used.
 X.rearranged.opt.row: see RA(); computed for N. used.

`VaR_bounds_hom()` for an “analytical” approach for computing best and worst Value-at-Risk in the homogeneous case.

`vignette("VaR_bounds", package = "qrmtools")` for more example calls, numerical challenges encountered and a comparison of the different methods for computing the worst (i.e., largest) Value-at-Risk.

Examples

```
### 1 Reproducing selected examples of McNeil et al. (2015; Table 8.1) #####

## Setup
alpha <- 0.95
d <- 8
theta <- 3
qF <- rep(list(function(p) qPar(p, shape = theta)), d)

## Worst VaR
N <- 5e4
set.seed(271)
```

```

system.time(RA.worst.VaR <- RA(alpha, qF = qF, N = N, method = "worst.VaR"))
RA.worst.VaR$bounds
stopifnot(RA.worst.VaR$converged,
          all.equal(RA.worst.VaR$bounds[["low"]],
                    RA.worst.VaR$bounds[["up"]], tol = 1e-4))

## Best VaR
N <- 5e4
set.seed(271)
system.time(RA.best.VaR <- RA(alpha, qF = qF, N = N, method = "best.VaR"))
RA.best.VaR$bounds
stopifnot(RA.best.VaR$converged,
          all.equal(RA.best.VaR$bounds[["low"]],
                    RA.best.VaR$bounds[["up"]], tol = 1e-4))

## Best ES
N <- 5e4 # actually, we need a (much larger) N here (but that's time consuming)
set.seed(271)
system.time(RA.best.ES <- RA(alpha, qF = qF, N = N, method = "best.ES"))
RA.best.ES$bounds
stopifnot(RA.best.ES$converged,
          all.equal(RA.best.ES$bounds[["low"]],
                    RA.best.ES$bounds[["up"]], tol = 5e-1))

### 2 More Pareto examples (d = 2, d = 8; hom./inhom. case; explicit/RA/ARA) ###

alpha <- 0.99 # VaR confidence level
th <- 2 # Pareto parameter theta
qF <- function(p, theta = th) qPar(p, shape = theta) # Pareto quantile function
pF <- function(q, theta = th) pPar(q, shape = theta) # Pareto distribution function

### 2.1 The case d = 2 #####

d <- 2 # dimension

## ``Analytical``
VaRbounds <- VaR_bounds_hom(alpha, d = d, qF = qF) # (best VaR, worst VaR)

## Adaptive Rearrangement Algorithm (ARA)
set.seed(271) # set seed (for reproducibility)
ARAbest <- ARA(alpha, qF = rep(list(qF), d), method = "best.VaR")
ARAworst <- ARA(alpha, qF = rep(list(qF), d))

## Rearrangement Algorithm (RA) with N as in ARA()
RAbest <- RA(alpha, qF = rep(list(qF), d), N = ARAbest$N.used, method = "best.VaR")
RAworst <- RA(alpha, qF = rep(list(qF), d), N = ARAworst$N.used)

## Compare
stopifnot(all.equal(c(ARAbest$bounds[1], ARAbest$bounds[2],
                    RAbest$bounds[1], RAbest$bounds[2]),
                  rep(VaRbounds[1], 4), tolerance = 0.004, check.names = FALSE))

```

```

stopifnot(all.equal(c(ARAworst$bounds[1], ARAworst$bounds[2],
                    RAworst$bounds[1], RAworst$bounds[2]),
                  rep(VaRbounds[2], 4), tolerance = 0.003, check.names = FALSE))

### 2.2 The case d = 8 #####

d <- 8 # dimension

## ``Analytical''
I <- crude_VaR_bounds(alpha, qF = qF, d = d) # crude bound
VaR.W <- VaR_bounds_hom(alpha, d = d, method = "Wang", qF = qF)
VaR.W.Par <- VaR_bounds_hom(alpha, d = d, method = "Wang.Par", shape = th)
VaR.dual <- VaR_bounds_hom(alpha, d = d, method = "dual", interval = I, pF = pF)

## Adaptive Rearrangement Algorithm (ARA) (with different relative tolerances)
set.seed(271) # set seed (for reproducibility)
ARAbest <- ARA(alpha, qF = rep(list(qF), d), reltol = c(0.001, 0.01), method = "best.VaR")
ARAworst <- ARA(alpha, qF = rep(list(qF), d), reltol = c(0.001, 0.01))

## Rearrangement Algorithm (RA) with N as in ARA and abstol (roughly) chosen as in ARA
RAbest <- RA(alpha, qF = rep(list(qF), d), N = ARAbest$N.used,
             abstol = mean(tail(abs(diff(ARAbest$opt.row.sums$low)), n = 1),
                           tail(abs(diff(ARAbest$opt.row.sums$up)), n = 1)),
             method = "best.VaR")
RAworst <- RA(alpha, qF = rep(list(qF), d), N = ARAworst$N.used,
              abstol = mean(tail(abs(diff(ARAworst$opt.row.sums$low)), n = 1),
                            tail(abs(diff(ARAworst$opt.row.sums$up)), n = 1)))

## Compare
stopifnot(all.equal(c(VaR.W[1], ARAbest$bounds, RAbest$bounds),
                  rep(VaR.W.Par[1],5), tolerance = 0.004, check.names = FALSE))
stopifnot(all.equal(c(VaR.W[2], VaR.dual[2], ARAworst$bounds, RAworst$bounds),
                  rep(VaR.W.Par[2],6), tolerance = 0.003, check.names = FALSE))

## Using (some of) the additional results computed by (A)RA()
xlim <- c(1, max(sapply(RAworst$opt.row.sums, length)))
ylim <- range(RAworst$opt.row.sums)
plot(RAworst$opt.row.sums[[2]], type = "l", xlim = xlim, ylim = ylim,
     xlab = "Number or rearranged columns",
     ylab = paste0("Minimal row sum per rearranged column"),
     main = substitute("Worst VaR minimal row sums (*alpha==a.*", "~d==d.*" and Par("th.*")", list(a = alpha, d = d, th = th)))
lines(1:length(RAworst$opt.row.sums[[1]]), RAworst$opt.row.sums[[1]], col = "royalblue3")
legend("bottomright", bty = "n", lty = rep(1,2),
      col = c("black", "royalblue3"), legend = c("upper bound", "lower bound"))
## => One should use ARA() instead of RA()

### 3 "Reproducing" examples from Embrechts et al. (2013) #####

### 3.1 "Reproducing" Table 1 (but seed and eps are unknown) #####

```

```

## Left-hand side of Table 1
N <- 50
d <- 3
qPar <- rep(list(qF), d)
p <- alpha + (1-alpha)*(0:(N-1))/N # for 'worst' (= largest) VaR
X <- sapply(qPar, function(qF) qF(p))
cbind(X, rowSums(X))

## Right-hand side of Table 1
set.seed(271)
res <- RA(alpha, qF = qPar, N = N)
row.sum <- rowSums(res$X.rearranged$low)
cbind(res$X.rearranged$low, row.sum)[order(row.sum),]

### 3.2 "Reproducing" Table 3 for alpha = 0.99 #####

## Note: The seed for obtaining the exact results as in Table 3 is unknown
N <- 2e4 # we use a smaller N here to save run time
eps <- 0.1 # absolute tolerance
xi <- c(1.19, 1.17, 1.01, 1.39, 1.23, 1.22, 0.85, 0.98)
beta <- c(774, 254, 233, 412, 107, 243, 314, 124)
qF.lst <- lapply(1:8, function(j){ function(p) qGPD(p, shape = xi[j], scale = beta[j])})
set.seed(271)
res.best <- RA(0.99, qF = qF.lst, N = N, abstol = eps, method = "best.VaR")
print(format(res.best$bounds, scientific = TRUE), quote = FALSE) # close to first value of 1st row
res.worst <- RA(0.99, qF = qF.lst, N = N, abstol = eps)
print(format(res.worst$bounds, scientific = TRUE), quote = FALSE) # close to last value of 1st row

### 4 Further checks #####

## Calling the workhorses directly
set.seed(271)
